It may be well to give some idea of the size of a condenser. One cubic foot of condenser will take about 2,000 volts and 5 amperes, or 10,000 apparent watts. With higher pressures the volume necessary is slightly less, and with low pressures the size increases. Below about 500 volts the bulk increases rapidly, as the volume of tinfoil is greater. The cost, therefore, increases too. It is possible to make condensers very much smaller than this; but while they are new it is best to allow a large factor of safety. Choking coils and constant-current transformers for arc lamps are not the only things requiring exciting currents. Transformers, especially if made with open iron circuits, take "idle" currents, and this can be supplied in the same way. Nearly the whole of an open-circuit exciting current can be supplied by condensers. There is always some left over, because the E.M.F. never varies exactly harmonically. Even if it did, there is some loss in the iron, so the no-load current cannot be reduced to nothing. In a closed-circuit transformer the no-load current is less to begin with, but the active component is much greater, so that it cannot be reduced so much by condensers. It can generally be about halved.

The next use for condensers, which is analogous to those already described, is in connection with motors. Of course it is a little difficult to say what the alternate-current motor of the future will be like. If it is a synchronising machine, with the magnets

* From *Industries*.

Digitized by Google

excited by a direct current, it may take a leading or a lagging current, or one in step with the pressure. If it has field-magnets excited by an alternate current it will take a lagging current, and condensers will be necessary. Nearly all the multiple-current motors take large exciting currents, so condensers will be necessary in their case. Take the case, for instance, of the Dobrowolsky 2 H.P. motor, as it is the only case whose figures have been published; at no load it takes 70 volts and 30 amperes at 35 periods per second. This current is presumably in both circuits, so that the apparent power is 4,200 watts; at full load it takes 70 volts and 100 amperes in each circuit, or 14,000 apparent watts. It, therefore, requires two condensers to reduce the apparent watts to about a tenth of these values. The enormous exciting current taken by this form of motor is one of its greatest disadvantages. A condenser to supply 14,000 apparent watts at a frequency of 35 would have a volume of 4 cubic feet. If the frequency is raised to 100 the exciting current increases at approximately the same rate, and so the condenser remains the same size. As there is some difficulty in making the large low-pressure condensers, it is best from that point of view to put the condenser on the high-pressure side of the transformer. This, unfortunately, demands that the transformer should be ten times the size. Thus, a 2 H.P. motor of this type would demand a 20 H.P. transformer at a frequency of 35, or a 60 H.P. at 100 periods per second. The transformers are nearly the same size in these two cases. The enormous size of the transformers is a great drawback to machines excited by alternate currents, and, unless multiple current motors can be greatly improved, this fault alone would be enough to render them useless for most work.

So far the condenser has been described as arranged in shunt to the circuit containing self-induction. It has then no effect on the circuit with self-induction, but affects the dynamo. In fact, it supplies exciting current, instead of letting the dynamo supply it. The self-induction can, however, be counteracted by arranging capacity in series with it. For instance, suppose the alternate machine is made like one for direct currents, except that the field-magnets are laminated. Suppose the machine in question is a 10-H.P. motor for 100 volts. If the field-magnets are wound to suit 100 volts on a direct-current circuit, they will be only very slightly excited by the alternating pressure. If the number of turns is much reduced and the diameter increased, full excitation will eventually be reached, but the current will be enormous. For instance, if the magnets take 2 amperes on a 100-volt direct-current circuit, the loss in copper is 200 watts; but to drive 2 amperes through the inductive circuit with an alternate current would probably need something like 5,000 volts. If a few turns of large wire are used instead, the full excitation will probably be reached with about 100 amperes. Not only is the exciting current enormous, but the armature current is not in step with the field induction, therefore the output is also lessened from this cause. M. Leblanc was the first to point out a method of overcoming these troubles by the use of condensers. A condenser may be put in series of such a capacity that at the frequency employed the E.M.F. of the condenser is always exactly equal and opposite to that of the self-induction of the magnets. This condition can only be attained approximately, since the pressure does not vary perfectly harmonically. If it did, all the E.M.F. of the supply circuit would be spent on resistance, so that the same current would be produced as if the magnets were excited by a direct pressure. The field induction is then in step with the E.M.F., so that the armature current is so also, and the power taken by the motor is found by multiplying the pressure by the current.

Messrs. Stanley and Kelly have designed and worked out a motor on this principle. It is constructed like an ordinary direct-current shunt motor, but has laminated field magnets. A condenser is arranged in series with the magnets. This motor has some drawbacks. In the first place, if the field magnets and armature are on a 100-volt circuit, the pressure on the condenser and on the field coils will be something like 5,000 volts, and this might make the motor too dangerous for admission to private premises. Of course, this depends on the size and design of the motor. It may be possible to design a machine with much lower condenser pressure. The loss by hyteresis in the field magnets is also necessarily large; but that is not such a serious matter in a motor as in a transformer which is in use day and night. The next trouble is sparking at the brushes. The armature coils are short-circuited just at the time of the most rapid change of field, so that there is a large current in the short-circuited section. I would suggest that this trouble can be overcome by winding the armature with two separate circuits in parallel. The brushes then collect from both, but never short-circuit any of the sections.

The Tesla motor, as is well known, demands two or more currents differing in phase. Two currents differing a quarter of a period will suffice. At first special dynamos with double-armature circuits were used as generators, but several arrangements involving condensers have been proposed. The first experiments of this kind were probably made by Prof. Ayrton and Dr. Sumpner. They had a small Tesla motor some years ago, but made up some arrangement with self-induction and capacity so as to split a single current into a double one. The experiments have not been published, therefore I do not know what the exact arrangement was. Mr. Tesla has designed numerous arrangements himself; but the most complete investigations have been made by MM. Leblanc and Hutin, and those interested in this subject will do well to read the able articles in the *Lumière Electrique* which have been appearing recently at short intervals. Those authors have gone most carefully and exhaustively into the whole subject of alternate-current motors of all sorts, and their Papers are very suggestive. In one a very simple arrangement is due to them. One field-magnet circuit has a condenser in series with it. Its current and induction are therefore in step with the pressure, and the wire used is the same as for direct currents under the same pressure. The other magnets, however, are wound with few turns of low-resistance wire, and take a large current, which lags practically a quarter of a period behind the pressure. In all practical cases a lag can be adjusted to a quarter of a period by using a condenser of the right capacity in the first circuit.

It is to be feared that there will be great difficulty in working out this system to be right at various loads. As the load increases, an active current should flow in both circuits. The circuit with the condenser in series with it cannot take its load current, so that the full load output in this form of motor may be little more than half that of a double-current motor of the same size. It is probable, however, that the ingenuity of MM. Hutin and Leblanc, in France, or Mr. Tesla, in America, may overcome this drawback. A multiple-current motor is, however, thus obtained, which will work on ordinary supply circuits Only one of the sets of magnets takes a large "idle" current; but to avoid trouble from this the use of a second condenser in shunt to the mains or to the transformer that supplies the motor is advisable. This condenser is of the same cubical contents as the first, but unless arranged on the high-pressure side of the transformer it is designed for a much lower pressure and for a correspondingly larger current. By this means a self-starting motor can be obtained which has no brushes, which works on an ordinary supply circuit, and which gives full torque on starting. It has, however, the same drawbacks as the type first described. The dangerous pressure on the field coils of the first circuit may be reduced by arranging the magnet coils in small portions alternately. If the fields take 5,000 volts to drive the exciting current through, say, twelve coils, the coils and portions of the condenser may be arranged alternately, so that the maximum pressure is just over 400 volts due to the condensers. The fall over the resistance of the circuit is out of step with this, and may therefore be neglected. Mr. Tesla has also patented an arrangement on the same principle as MM. Hutin and Leblanc. He uses one field circuit partly as a transformer to transform up, and then places the condenser in the secondary circuit. This seems rather to increase the difficulty arising from the very high pressures resulting from arranging condensers and induction coils in series. He has also put a condenser in the armature circuit, but it is difficult to see the inventor's object in this. Whether this form is the motor of the future or not is difficult to say; but if it is, the number of condensers required will be considerable, so we are justified in discussing it at some length in this article.

There is still another possible use for condensers, and that is for exciting dynamos. An alternate machine may be regarded as made up of two elements. One has constant induction, and is called the field magnet; the other is variable, and is called the armature. The field magnet may be excited by a direct current round it, or by an alternate current in the armature which is direct relatively to the field, because the armature changes position while the current changes its direction. As far as copper in the machine goes, it is cheaper to excite the fields by arranging the machine so as to have considerable armature reaction, and exciting by means of a condenser. Suppose when the field has its own coils the current density and weight of copper is the same in the field magnet and armature; if the field coils are removed and the condenser applied, the armature copper need not be doubled; it will carry the current at the same density as before, if the copper is increased in the proportion $\sqrt{2}:1$. The total power wasted is less than before; in fact, if the armature copper is not increased at all, the loss of power in the armature alone when the condenser is used is the same as that in the armamature and field-magnets together, with separate excitation. By the use of a condenser, cheapness, or higher efficiency, or a compromise of these can be obtained. The condenser itself is generally much cheaper than an exciter, and is, of course, very much more efficient. An alternate machine with a condenser follows practically the same laws as a shunt-wound dynamo, but it has only one copper circuit, and no commutator.

Perhaps enough has been said to show that condensers may have a large future. New possibilities are appearing every day, and there is no saying what combinations of capacity, self-induction, and resistance may be invented during the next few years.

SUMMARY OF ELECTRICAL EVENTS FOR 1891.

JANUARY.

The action brought by the British Tanning Company, owning the Worms and Balé patents for tanning by electricity, against Mr. Groth, also the patentee of a similar process, came before Mr. Justice Romer, who invalidated the Worms and Balé patent on a point of law, and further decided that the Groth process was essentially different to that of MM. Worms and Balé (14th, 15th, 16th).

Institution of Electrical Engineers. Presidential Address, by Prof. Crookes, F.R.S., on "Electricity in Transitu: from Plenum to Vacuum" (15th).

Death of M. Emile Reynier.

Meeting of the National Telephone Company, proposed issue of further capital in the shape of debentures (£300,000 to £350,000) (21st).

Great snowstorm in the United States, which caused general havoc among the telegraph, telephone, and electric light wires, but especially so in the State and City of New York (25th).

Public appeals by University College and King's College for £50,000 apiece to meet the increasing demand for scientific and engineering education (26th).

Bill introduced into the United States Senate sanctioning the incorporation of a Pacific Cable Company with a capital of $5,000,000, and authorising the United States Treasury to grant the Company an annual subsidy of $200,000 for 15 years (26th).

Press visit to the Elmore Works at Hunslet, near Leeds (27th).

St. James and Pall Mall Company accept a licence from the Lane-Fox Electrical Company under their distribution patent No. 3,988 of 1878.

The residents of Peckham and East Dulwich petition the City and South London Railway Company to run a branch line from the Elephant and Castle through their districts.

A Special Committee appointed by the London County Council recommend that body to devote £23,000 during the current year to the furtherance of technical education, and to raise £130,000 per annum by a 1d. rate for the same purpose.

Dividends declared: Anglo-American Telegraph Company, 2⅞ per cent.

FEBRUARY.

Paper on "Electric Mining Machinery," read before the Institution of Civil Engineers, by Ll. B. and C. W. Atkinson (3rd).

Inauguration of the lighting of the streets of the City of London by electricity, the Lord Mayor laying the foundation stone of the first junction box just outside the Mansion House (3rd).

Publication by the Board of Trade of the resolutions to be submitted to the Electrical Standards Committee (10th).

The London County Council reject, by a majority of five, the recommendation of its Special Committee, that the sum of £23,000 should be set aside from the beer and spirit duties and devoted to the furtherance of technical education (10th).

Registration of the City of London Electric Lighting (Pioneer) Company, with a capital of £100,000 in £50 shares. Chairman, the Lord Mayor.

Tenders for the electric lighting of Dublin awarded to the Irish House-to-House Company and the Electrical Engineering Company of Ireland (11th).

The Glasgow Corporation invite tenders for the carrying out of their Provisional Orders (13th).

Publication of the awards made by the International Niagara Commission in connection with the projects sent to them for the utilisation of 125,000 h.p. at Niagara, and its distribution.

Re-commencement of the Deptford Supply (16th).

Cantor lectures on the "Electric Transmission of Power," by Mr. Gisbert Kapp.

Prof. Helmholtz decorated with the Grand Cross of the Legion of Honour by the French Government.

Some important transmission of power experiments at a pressure of 25,000 volts carried out at Oerlikon.

Publication of the report of the Special Committee appointed by the Salford Corporation to investigate the best mode of treating sewage. The electrical process favourably reported on.

The United States Senate propose to subsidise a cable connecting the United States with Hawaii (16th).

Meeting of the National Electric Light Association at Providence (R.I.) (17th, 18th, 19th). Interesting Paper, by Prof. Elihu Thomson, on "The Electric Arc and its Use in Lighting."

Paper on "Transformer Distribution," by Mr. J. Swinburne, read before the Institution of Electrical Engineers (19th).

The Mutual Telephone Company open their first exchange in Manchester (28th).

Dividends declared: India Rubber, Gutta Percha, and Telegraph Works Company, 10 per cent.; St. James and Pall Mall Electric Light Company, 5 per cent.; Liverpool Electric Supply Company, 3½ per cent.; Telegraph Construction and Maintenance Company, 20 per cent.

MARCH.

The United States Senate reject the proposal to subsidise a cable connecting the United States with Hawaii (3rd).

The Central London Railway Bill came before a Select Committee of the House of Commons (3rd).

Friday evening lecture at the Royal Institution on "Electromagnetic Repulsion," by Dr. J. A. Fleming (6th).

The laying of the London-Paris telephone cable commenced (9th).

Bristol Town Council agree to the report of their Electrical Committee, recommending the adoption of the alternate-current transformer system, the construction of a 10,000-light station, and the erection of 100 arc lamps for street lighting, at an estimated cost of £66,000 (10th).

The Central London Railway Bill reported to the House (11th).

Godalming Town Council decide to spend £7,000 on electric lighting.

Completion of the operation of laying the London-Paris telephone cable (14th).

Absorption of the South of England Telephone Company by the National Company (16th).

First word spoken through the London-Paris telephone line (17th).

Rejection of the City and South London Railway (Islington) Extension Bill by the House of Commons Select Committee (17th).

London County Council Overhead Wires Bill passes through Committee (18th).

The three stations of the Westminster Electric Supply Corporation come into operation.

Dividends declared: Direct Spanish Telegraph Company, 7 per cent.; Brighton and Hove Electric Light Company, 5 per cent.

APRIL.

The London-Paris telephone line opened to the public (1st).

Overhead wire raid by the New York municipal authorities (1st).

Paper on "The Cost of the Generation and Distribution of Electrical Energy," read before the Institution of Civil Engineers, by Mr. R. E. B. Crompton (7th).

Paper on "The Design of Multipolar Dynamos," read before the Institution of Electrical Engineers," by Mr. W B. Esson (9th).

Important Papers on "Electric and Magnetic Screening," read before the Royal Society by Sir William Thomson, also one on "The Measurement of Power given by any Electric Current to any Circuit," by Prof. Ayrton and Dr. Sumpner (9th).

The action brought against the London Electric Supply Corporation, by Messrs. Savory and Moore, to restrain them from erecting a transformer sub-station at the Grosvenor Gallery, directed by Mr. Justice Kekewich to stand over for three months, to enable the defendants to take steps to render the upper stories of their building fireproof (14th).

Petition for the prolongation of the Jablochkoff distribution patent (No. 1,996 of 1877) came on for hearing before the Judicial Committee of the Privy Council. Owing to the discovery that the cover and the face of the patent were dated differently, and that the patent was consequently invalidated by prior publication, the case was adjourned until May 20th, to enable petitioners to amend their petition (15th).

Formation of an association for the protection of the London telephone subscribers (15th).

London Overhead Wires Bill read a third time in the House of Commons (17th).

Central London Railway Bill read a third time in the House of Commons (20th).

Paper read before the Institution of Electrical Engineers, by Major P. Cardew, R.E., on "A Few Calculations on Electrical Shocks from Contact with High-pressure Conductors" (23rd).

Dividends declared: Oriental Telephone Company, 2¼ per cent.; Eastern Extension Australasia and China Telegraph Company, 7 per cent.; Indo-European Telegraph Company, 10 per cent.; Reuter's Telegram Company, 5 per cent.; Submarine Cables Trust, 6 per cent.

MAY.

Reductions, averaging over 50 per cent., in the cable rates to the colonies of Western Australia, South Australia, Victoria, New South Wales, and Tasmania (1st).

Inauguration of a Central Station supplying the Place Clichy district on the 5-wire system.

Digitized by Google

Decision of the Conseil d'État in favour of the Anglo-American Telegraph Company in its action against the Paris-New York Cable Company (1st).

Successful public trial in Philadelphia of the Waddell-Entz alkaline traction accumulator (4th).

Paper read before the Institution of Electrical Engineers, by Dr. J. A. Fleming, on "Some Effects of Alternating-Current Flow in Circuits having Capacity and Self-Induction" (7th).

Paper read before the Institution of Electrical Engineers, by Mr. W. H. Preece, on "Some Points Connected with Mains for Electric Lighting" (7th).

Death of M. Edmond Becquerel (11th).

Petition for the prolongation and confirmation of the Jablochkoff distribution patent No. 1,996 of 1877, rejected by the Judicial Committee of the Privy Council (13th).

Paper read before the Old Students' Association, by Mr. E. B. Vignoles, on "Some Researches in Electro-magnetic Induction" (13th).

Paper read before the Institution of Electrical Engineers, by Mr. R. E. Crompton, on "The Most Economical Mode of Feeding a Low-Pressure Network" (14th).

Opening of the Frankfort Electrical Exhibition (16th).

Meeting of the American Institute of Electrical Engineers (19th, 20th, 21st).

National Telephone Company *v.* Muirhead. An action brought in the Scotch Courts to restrain defendant from supplying Ader and Berthon transmitters, and to obtain damages. Settlement arrived at (20th).

Announcement of awards in the Paris Municipality's electric meter competition. 1st prizes, *ex æquo*, Aron and Elihu Thomson meters; 2nd prizes, Frager and Marès meters (31st).

Opening of the Notting Hill Electric Lighting Company's station (31st).

Dividends declared: Great Northern Telegraph Company, 8·6 per cent.; Western and Brazilian Telegraph Company, 5 per cent.; West Coast of America Telegraph Company, 2½ per cent.; Consolidated Telephone Construction and Maintenance Company, 6 per cent.

JUNE.

Death of Mr. David Brooks, of Philadelphia (1st).

London Overhead Wires Bill, also Bill reviving Worms and Balé patent for electrical tanning, passed.

Paper on "Electrical Evaporation," read before the Royal Society, by Prof. W. Crookes; also two on "The Chemistry of the Secondary Cell," by Mr. G. H. Robertson and Prof. H. E. Armstrong (11th).

Celebration of the Centenary of Faraday's birth. Delivery of addresses at the Royal Institution on Faraday's electrical work, and on Faraday's chemical work, by Lord Rayleigh and Prof. Dewar respectively (11th and 26th).

Electrical disturbances at the Greenwich Observatory due to the City and South London Railway.

Deputation from the Associated Chambers of Commerce to the Board of Trade, urging the adoption of a complete system of electrical communication with lighthouses (12th).

Cambridge Town Council decide to erect a 10,000-light municipal electric lighting plant (16th).

Allison *v.* City and South London Railway. Action for damages and injunction to restrain Company from working their generating plant. Nuisance due to condensed steam, noise, and vibration proved. Company given two months to mitigate the same (16th, 17th, 18th).

Preamble of the Central London Railway Bill proved to the satisfaction of the House of Lords Select Committee (24th).

Death of William Edward Weber, at Göttingen (24th).

The streets of Carlow lighted by electricity (25th).

Trial run of the street lights in a portion of the City (25th).

Dividends declared: Anglo-Portuguese Telephone Company, 5 per cent.; West African Telegraph Company, 5 per cent.

JULY.

Royal Assent given to the London County Council's Overhead Wires Bill (3rd).

Conversazione of the Institution of Electrical Engineers (6th).

In the action brought in the United States by the Edison Electric Light Company against the United States Electric Lighting Company, decision given in favour of the Edison lamp patent (14th).

Successful experiments at Thames Ditton to show possibility of parallel running with Mordey alternators and Willans direct couple engines (14th).

Death of Mr. Willoughby Smith (16th).

Issue of a Board of Trade report showing that 58 Provisional Orders (34 to Local Authorities, 24 to Companies) have been granted.

Huddersfield Corporation accept Brush Company's tender for electric lighting station.

The action brought in the United States by Mr. Brush against the Electrical Accumulator Company terminated in a decision favourable to the claims of Mr. Brush (23rd).

Termination of the lighting of the streets of Barnet by means of glow lamps.

Dividends declared: National Telephone Company, 6 per cent.; Direct United States Cable Company, 3½ per cent.; Eastern Telegraph Company, 6½ per cent.; Edison-Swan United Electric Light Company, A shares, 7 per cent.; Globe Telegraph and Trust Company, 5¼ per cent.; Crompton and Co., 8 per cent.; Manchester Edison-Swan, 5 per cent.

AUGUST.

First half-yearly meeting since the opening of the line of the shareholders of the City and South London Railway. Chairman stated that 2,412,343 passengers had been carried, and 141,408 train-miles run. The receipts amounted to £19,688, and the expenses £15,520 (11th).

New cable laid between England and Germany (Bacton-Emden).

At the half-yearly meeting of the shareholders of the Liverpool Overhead Railway the definite adoption of electric traction and the conclusion of a contract with the Electric Construction Corporation to work the line for 3½d. per train mile (locomotive expenses) were announced (12th).

Resolution passed increasing the entrance and transfer fees of the Institution of Electrical Engineers (13th).

Sixty-first meeting of the British Association at Cardiff (19th).

Publication by the Birmingham Central Tramways Company of some satisfactory and important figures with regard to their accumulator cars.

Formation of the Electric Welding Company, with a capital of £460,000.

Death of Mr. Edward Gilbert, well-known telegraph engineer.

Death of the Postmaster-General (24th).

Successful preliminary trials of the Lauffen-Frankfort electric transmission of power plant.

Publication of the Report of the Board of Trade Electrical Standards Committee.

Death of Mr. John Louis Crossley (30th).

Dividends declared: Cuba Submarine Telegraph Company 8 per cent.

SEPTEMBER.

The Manchester Corporation decide to apply to the Local Government Board for permission to borrow £150,000 to carry out the proposed electric lighting scheme (3rd).

Opening of the Frankfort International Electrical Congress (7th).

Meeting of the National Electric Light Association at Montreal (7th, 10th).

Inauguration of the Brighton Municipal Central Station (14th).

Lengthy correspondence in *The Times* relating to the London telephone service; announcement by the Duke of Marlborough of a proposed competitive system by the New Telephone Company.

The South Staffordshire Tramways Company decide to work their system by electricity.

The Cork Consumers' Company decide to obtain an electric lighting Provisional Order.

Dividends declared: Brush Electrical Engineering 6 per cent. (half-year).

OCTOBER.

Decision of the Austrian Government to purchase the system of the Telephone Company of Austria.

Death at Florence of the Abbé Jean Caselli, inventor of the *pantelegraph*.

Close of the Frankfort Exhibition (19th).

Street Railway Convention at Pittsburgh (21st, 22nd, 23rd).

Opening of an electric tramway at Leeds 3½ miles long, overhead wires, Thomson-Houston motors, &c. (29th).

The Rothschilds place 175,000 francs at the disposal of MM. Hutin and Leblanc to carry out large scale experiments with their rotary field motor.

The American Patent Office decide against the Drawbaugh telephone patent applied for in July, 1880, on the ground that the invention in controversy was anticpated by Edison (25).

Dividends declared: Crompton Electric Supply Company of Australia, 7 per cent.

Digitized by Google

NOVEMBER.

St. Pancras Vestry's central lighting station comes into operation (9th).

The Brecon Town Council decide to run an electric railway up the Beacons.

The Glasgow Town Council decide to take over the tramway system of the City in 1894 (12th).

The City of London Electric Lighting Company apply for an extension of one year in the time allowed for completing their street lighting contract (17th).

The Berliner microphone "interference" case decided. The patent applied for in June, 1877, issued November 17, 1891.

The Brighton Town Council refuse to purchase the goodwill of the Brighton and Hove Electric Light Company's undertaking for the sum of £7,000 as recommended by the Lighting Committee (19th).

Dividends declared: Woodhouse and Rawson United, 15 per cent.; Swan United Electric Light Company, 11 per cent.; Blackpool Electric Tramway 7½ per cent.

DECEMBER.

Prof. Ewing communicated to the Cavendish Physical Society the results of some experiments undertaken by him to determine whether or no the hysteresis losses in a transformer decrease as the load increases. He found no indication whatever of such a phenomenon (1st).

The Commissioners of Sewers refuse the application of the City of London Electric Lighting Company for an extension of time for carrying out the public lighting of the City (1st).

The London County Council refuse to lend the vestry of St. Pancras the £60,000 required by them to carry out their electric lighting scheme, and recommend them to borrow elsewhere (1st)

Important paper on "Secondary Batteries," read before the Society of Arts by Mr. G. H. Robertson (2nd).

The Nottingham Town Council empower their special committee to spend from £25,000 to £30,000 in lighting a central section of the borough by electricity.

The Board of Trade, in conjunction with the London County Council, the Corporation, and the Gas Companies, decide to appoint a committee to consider the question of a proper standard of light.

The National Telephone Company complain to the Leeds Corporation that their service is interfered with by the working of the Roundhay Park electric tramway. After hearing both sides the Corporation decide to let the two Companies settle the matter between them (7th).

The Richmond Town Council seal a contract with Messrs. Latimer, Clark, Muirhead, and Co. for the electric lighting of the borough (8th).

The London County Council approve a set of bye-laws drawn up in accordance with the London Overhead Wires Act, 1891 (8th).

The Electric Trade Section of the London Chamber of Commerce circularise members with regard to getting up a petition to the President of the Board of Trade against the decision of his department not to allow any overhead wires as a permanency (9th).

Prof. W. E. Ayrton, F.R.S., elected President of the Institution of Electrical Engineers for 1892. Institution premium awarded to Messrs. C. G. Lamb, E. W. Smith, and M. W. Woods; Paris Electrical Exhibition premium to Mr. J. Swinburne: Fahie premium to Mr. P. V. Luke (10th).

A Paper "On the Specification of Insulated Conductors for Electric Lighting and other purposes," read before the Institution of Electrical Engineers, by Mr. W. H. Preece (10th).

The City of London Electric Lighting Company commences the supply of current for private lighting (14th).

Bradford Town Council decide to extend municipal electric lighting area (15th).

Prof. Dewar communicated to the Royal Society the fact that he had discovered liquid oxygen at a temperature of −180° C. to be highly magnetic.

Mr. Justice Kekewich, at the suit of Messrs. Savory and Moore, grants an injunction against the London Electric Supply Corporation restraining them from using their Grosvenor Gallery premises as a transformer sub-station (18th).

Demonstration of the improved Benardos process of electric arc welding at Coombs Wood Works, Birmingham, by Messrs. Lloyd and Lloyd (21st).

Dividends declared: Electric Construction Corporation, 6 per cent.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 21, 1891.

Issue of a Fundamental Electric Railway Patent.—The United States Patent Office has again distinguished itself. Right upon the heels of the Berliner patent comes the issue of the final documents on the fundamental electric railway patent on an application dated 12 years ago. Investigation discloses a very interesting chapter in the history of the electric railroad. The patent itself covers broadly an electric railroad having a conducting circuit formed wholly or in part by the rails. The patentee is George F. Green, of Kalamazoo, Michigan. His work has been investigated with reference to its being used in some of the electric railway patent suits now in progress; and from what has been ascertained, it would appear that Mr. Green is the first American worker seriously to take hold of the problem since the early days when divers primary battery model roads were made. He is a poor workman, who has obtained his livelihood by making window sashes and blinds; his spare time being largely occupied by electrical experiments. For more than 20 years he has had the electric railway on his mind, and about 1875 built a little track a couple of hundred feet long, and of six or eight inch gauge, on which a model train was operated. The motive power was derived from a storage battery connected with the rails, the apparatus was operated by a motor of his own construction. This railway was displayed to his fellow-townsmen, and he made some effort to exploit it, but with no results; and about 1879 he built a model road on a larger scale, still operated by storage batteries, however; and on August 15th of that year he put in his application for a patent. He was so poor that he endeavoured to act as his own attorney, and consequently met with great obstacles in the Patent Office. The patent was rejected, even on appeal to the Commissioner, and was appealed from the Patent Office to the Circuit Court of the District of Columbia, the only tribunal that can order the issue of a patent after the decision of the Commissioner against it. He was in interference with Field, Hall, and others; but finally on December 8, the patent, after many vicissitudes and changes in the office, was issued in pursuance of an order of the Court. He had proposed to use a dynamo instead of storage batteries, but none was available. Although the patent in view of the many anticipations of primary battery days probably possesses no commercial importance, it forms a very interesting addition to the history of the electric railway, inasmuch as it establishes Mr. Green's priority in the general idea as against those of the various workers who entered the field about 1879. His work forms the connecting link between the electric roads proposed at various times from 1840 to 1860 and the electric traction of to-day, so that; historically speaking, the recognition of his rights by the Patent Office is of no small interest.

The Cuttriss Telephone Transmitter.—Apropos of the Berliner patent, it is interesting to note that Mr. Charles Cuttriss, of New York, has just patented a telephone transmitter, in which the variation of current is accomplished by the variation of tension on a spiral spring made of carbon. It is said to work admirably, and may prove a valuable addition to the list of telephonic apparatus, particularly in view of the Berliner claims.

Edison Stations in New York.—As an item of news in electric lighting, it may be mentioned that the Edison Illuminating Company has now connected all its stations in New York, forming a complete network extending from 59th Street to the Battery, and under complete control from the 26th Street Station, at which the pressure wires are concentrated. Up to two or three months ago the stations were independent, but the cross connections are now completed.

The Edison General Electrical Company.—Many rumours are afloat just now regarding possible changes in the management of the Edison General Electric Company. It is hard to say what truth there is in the various reports that have obtained credence in electrical circles and on Wall-street; but the feeling seems to be general that something is impending—what, will have to be determined after the annual meeting early in January. All the rumours suggest the withdrawal of Mr. Villard.

PUBLIC COMPANIES WOUND UP IN 1891.

Amongst the public companies wound up during the past year are the following:—

Allchin, Linnell, and Co., Limited.
Alterion Company, Limited.
Automatic Standard Screw Company, Limited.
Cadogan Electric Light Company, Limited (reconstructed as the New Cadogan and Belgrave Electric Supply Company, Limited).
City of London Electric Lighting (Pioneer) Company, Limited (transferred to the City of London Electric Lighting Company, Limited).
Devon and Cornwall Electric Light and Power Company, Limited.
Electrical Engineering Corporation, Limited.
Electro-Metallurgical Company, Limited.
Excelsior Copper Company, Limited (reconstructed as the Leeds Copper Company, Limited).
General Zinc Recovery and Lighting Company, Limited.
India-Rubber Estates Company, Limited.
Institute of Medical Electricity, Limited.
Protean Battery Syndicate, Limited.
Simplex Electrical Syndicate, Limited.
South of England Telephone Company, Limited (amalgamated with the National Telephone Company, Limited).
Woodhouse and Rawson Electric Manufacturing Company, Limited (amalgamated with Woodhouse and Rawson United, Limited).
Woodhouse and Rawson Electric Supply Company of Great Britain Limited (amalgamated with Woodhouse and Rawson United, Limited).

NEW PUBLIC COMPANIES OF 1891.

The following are the more important electrical and engineering limited liability companies registered during the past year, with their capital:—

Name of Company.	Capital.
Agence Dalziel	£60,000
Albert Electric Lighting Company	10,000
Albert Hoster	2,000
Alexander Mathieson and Sons	120,000
Anders, Elliot and Chetham-Strode.....	5,000
Arc Accumulator Company	1,000
Art Workshops	30,000
Aspinall's Enamel	125,000
Atéliers Hoster de St. Nicolas	2,000
Atlas Carbon Manufacturing Company	2,000
Aurora Electric Lighting and Distribution Company	25,000
Babcock and Wilcox	240,000
Benfield.....	50,000
Bicester Electricity Company	5,000
Birmingham Telegraph Factory	50,000
Blaikie Brothers	30,000
Bournemouth and District Electric Supply Company	50,000
Boy Messengers and Electric Call Company	200,000
British Electric Installation Contractors	20,000
British Electro-Chemical Agency.....	75,000
British Electrolytic Syndicate	100,000
British Hydraulic Foundry Company	200,000
Brown's Engine Company	15,000
Caledonian Telephone Company	50,000
Carbon Electric	20,000
Chloride Electrical Storage Syndicate.....	262 500
City of Bath Electric Lighting and Engineering Company	60,000
City of London Electric Lighting Company	800,000
City of London Electric Lighting (Pioneer) Company	100,000
City of Waterford Electric Supply Company.....	1,000
Collier Audible Telephone Syndicate	9,000
Concentric Seamless Steel Tube Company	20,000
Connelly Motor Company	70,000
County of London Electric Lighting Company	100,000
Crystal Palace District Electric Supply Company (name changed from the Electric Installation and Maintenance Company)...	100,000
Cuttriss, Wallis and Co.	10,000
Dermatine Company	55,000
Dobson and Barlow.....	750,000

Name of Company.	Capital.
East London Electric Supply Company	£1,000
Electrical Advertising Syndicate	10,000
Electrical Assets Purchase Company	1,000
Electrical Finance Corporation	100,000
Electrical Inventions Company.....	35,000
Electric Welding Company	460,000
Electrolytic Caustic Soda and Chlorine Trust	10,000
"Energy" Gas Electric Lighting and Power Company	20,000
"Engineering"	180,000
Epstein Electric Accumulator Company	101,000
European Sime-Edison Electrical Torpedo Company	201,000
Fibrate Syndicate	15,000
Foreign and Colonial Arc Accumulator Company	1,000
Fowler Insulator Syndicate	6,000
Froude-Hurrell Torpedo Company	10,000
Globe Electric Company.....	10,000
Gloucester Electricity Supply Company	100

Walker (Henry) and Son	50,000
John Warner and Sons	40,000
Weybridge Electric Supply	15,000
Whessoe Foundry Company	50,000
William Melburn and Sons	20,000
Alex. Wilson and Company	20,000
Wyleys	60,000
Wyndham Electric Light Company	1,500

CORRESPONDENCE.

"INDUCTANCE" AND "HINDRANCE."

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the recent Physical Society's discussion, I would suggest that if a name is really wanted for the companion to resistance in the impedance formula, the name proposed by me in *The Electrician* (August 17, 1888, p. 480) might be found suitable, namely, "hindrance."

To those who feel inclined to transfer the name "inductance" from inductance to hindrance (as above used) I would point out that although the matter is obscured and nonsensified in the irrational system of units, yet in my rational system inductance is a proper physical quantity in the same manner as conductance and permittance, depending upon a specific property of the material first (the inductivity, or the conductivity, or the permittivity), and upon the dimensions, &c., of the material or ethereal region considered. (*See* §§ 26 to 32 of "Electromagnetic Theory.")

Here 4π cropped up, of course. Now, regarding this, although (with the exception of an incidental remark) I should not have imagined it from what has appeared in this journal, yet I learnt from the *Electrical Review* lately that people were being exercised in their minds on the subject. This is as it should be. But there are three stages to salvation: first, you must be exercised in your mind until you come to recognise your sins; next, you must go on exercising your mind until you repent; lastly, you must keep on exercising your mind until you reform.

It is to be hoped, for the credit of electricians, that the third stage will be reached without needless postponement—to the next century, for instance. The longer the delay, after the second stage is passed, the worse will it be. The matter is of far greater intrinsic importance than any question of names.

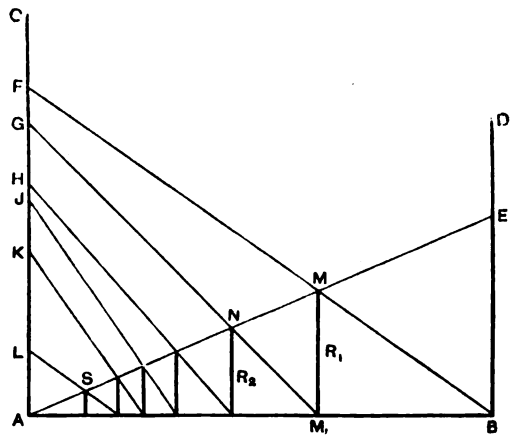
—Yours, &c., OLIVER HEAVISIDE.

Paignton, Devon, December 26, 1891.

THE COMBINED RESISTANCE OF CONDUCTORS IN PARALLEL.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to Fig. 2 in your article in *The Electrician* of the 18th inst., on "The Combined Resistance of Conductors in Parallel," I enclose a diagram on the principle shown applied to seven conductors instead of two only, as in your figure, and it certainly works out with extreme simplicity.



The construction of the diagram is as follows:—On any base of convenient length—A B—erect two perpendiculars—A C and B D. On B D set off a length—B E—to a suitable scale to represent the resistance of one of the parallel conductors; and on A C set off the lengths A L, A K, &c., representing all the other conductors. Taking the greatest of these—A F—and B E, draw the diagonals A E and F B and find the resultant resistance R_1, as in your diagram. From M_1 draw M_1 G, intersecting A E in N; and from N let fall the perpendicular R_2, the resultant of R_1 and A G. Proceeding thus, the point S is finally reached, which gives the total resistance of the whole seven conductors in parallel. For the purpose of ascertaining what extra conductor is required to bring the group down to a certain definite resistance, it is only necessary to take a point in A E at a vertical distance from A B equal to the desired total resistance, and to draw a straight line from the foot of the last resultant through this point till it cuts A C. The portion of A C thus marked off represents the resistance of the additional conductor needed.—I am, &c.,

December 24, 1891. W. S. BOULT.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your leading article of December 18th, under the attractive title, "Does Electricity Exist?" after referring to an illustration which represents a current of electricity passing through a voltameter as like to a stream of visitors passing through a turnstile, you say:—

> "When a hundred persons have passed, they can be collected, counted, and seen; they exist. When a coulomb has passed through a voltameter, where is it?"

This question seems to suggest that, in the respect referred to, the illustration fails; and that when a hundred coulombs have passed through a voltameter, they do not any longer exist, and cannot any longer be counted, like the people who have passed through a turnstile. But surely this is not so. A hundred coulombs passing through a voltameter all come out at the negative electrode; and an amperemeter, suitably placed in the circuit beyond that point, will count them all as they pass. Moreover, you may let them flow through a second voltameter, and they will do in it the same work as they did in the first; just as the people who pass through one turnstile may afterwards pass through a second. It would seem, then, that so far as this aspect of the question is concerned, the illustration of the turnstile and the people passing through it may be applied to the voltameter and the coulombs.

But my chief object in writing, at present, is to say a few words on the main subject of your article, the existence of

Digitized by Google

electricity. If you will kindly allow me, I should like to take the opportunity of stating the question in the form under which it has, for some time, presented itself to my mind. There is a remarkable analogy between a current of electricity and two other familiar forms of energy, as regards the way in which they do work. When work is done by heat, the heat must fall from a higher to a lower temperature; when work is done by falling water, the water must fall from a higher to a lower level; and when work is done by a current of electricity, the electricity must fall from a higher to a lower potential. But if we compare heat and falling water, under another respect, we find a striking contrast between them. When heat does work, a certain portion of the heat disappears; and the work done is the equivalent of the heat that has ceased to exist. Hence we regard heat as a form of energy, because the heat itself is expended in doing the work. On the other hand, when work is done by falling water, no part of the water ceases to exist; and from this we infer that the energy, in this case, does not consist in the water itself, but in the fact that it exists at a higher level, under conditions which allow it to fall to a lower level.

The question then suggests itself, does the energy of the electric current, in this respect, resemble the energy of falling water, or does it resemble the energy of heat? The answer clearly is, that it does not resemble the energy of heat, but the energy of falling water. When a current of electricity passes through a glow lamp, and does work by keeping it alight, the quantity of electricity that comes out at one end is exactly the same as the quantity that goes in at the other; but it comes out at a lower potential, just as a stream of water, after turning a mill, comes out at a lower level. Electrical energy, then, consists in the existence of electricity at a higher potential, under conditions which allow it to fall to a lower potential.

These conceptions seem to me, in some degree, to clear the ground for approaching the question you have raised. But that question still remains: What is that thing which we measure in coulombs, and call quantity of electricity; which we can raise to a higher potential by the expenditure of work; and which, in falling again to a lower potential, gives us back work in return? Is it matter, or is it motion, or is it something different from both, and as yet unconceived?—Yours faithfully,

GERALD MOLLOY.

Catholic University, Dublin, December 22, 1891.

THE THEORY OF THE WIMSHURST MACHINE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The letter of Mr. Gray which appeared in your issue of December 11th contains a few points of theory which I think it may be useful to settle.

1. The uprights of the Wimshurst machine may be of metal (Bréguet pattern), and not of dry wood; in either case the two diametrical conductors are in metallic contact with each other; in multiple plate machines the brush-holders are in two halves. These organs can, therefore, only play an essentially passive part, which consists in putting the sectors to earth.

2. "When the number of sectors is reduced below a certain limit (say eight), the machine will not excite itself, but will work if a charge is imparted to it from an external source" (*see* Gray's "Electrical Influence Machines," p. 222). The machine can even be made without carriers, with bare glass plates. The theory of the Wimshurst machine and of its auto excitation are therefore totally different. The first is evidently peculiar to the Wimshurst machine, the second is common to all armature machines—Bennett, Toepler, Voss, Thomson, &c.

3. When a carrier in contact with a brush receives a negative charge by lateral induction, all the preceding sectors are positively electrified, and all those which follow it are in a neutral state. When several negative sectors have left the brush, their action is always less than that of the positive sectors, since: (i.) They are fewer in number; (ii.) Each individual charge is smaller than that of each individual positive sector. When all the sectors are electrified, lateral induction ceases to play an active part, owing to the predominating action of the sectors on the second plate, and to the symmetry of the opposite actions. This, at least, is what seems to me the most probable.

As to the question of priority raised by Mr. Gray, I will not return to it again. I have quoted the author's very words, and I therefore think it useless to press the matter further.—I am, Sir, &c.,

G. PELLISSIER.

Paris, December 22, 1891.

EFFECTS OF ALTERNATE-CURRENT FLOW IN CIRCUITS HAVING CAPACITY AND SELF-INDUCTION.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In the abstract of my Paper before the Physical Society on the 18th inst., printed in your last number, there is an error I should like to correct.

It is stated that in the experiment on the 100 k-w alternator, concentric cable, and 18 k-w transformer, the rise of pressure at the alternator terminals, observed on connecting the cable to them, was the same whether the transformer was loaded or unloaded. The facts are as follows:—The rise of pressure at the alternator terminals was—as far as could be observed—the same when the cable was connected to them, whether the transformer at the far end of the cable was in circuit or not, when the transformer secondary was open, or had only about a dozen 16 c.p. lamps as a load.—Yours, &c.,

Dec. 30, 1891. HAMILTON KILGOUR.

ROUNDHAY PARK ELECTRIC TRAMWAY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: On page 189 of your issue of December 25th, under the heading of the "Roundhay Electric Tramway," you state *apropos* of the accident upon my line during the fog on Monday, that it was about "an hour and a-half before the traffic could be resumed, the line being strewn with *débris*." A similar notice appeared in the *Daily Telegraph*, but I did not think it worthy of contradiction. Allow me, in the first place, to draw your attention to the fact that it would take a very large tram-car to furnish *débris* to block a tram line for an hour and a-half; and, secondly, to correct your statement by assuring you that within ten minutes after the accident both cars had run themselves into the car shed, no damage having been done, beyond smashing the front platforms of each car and breaking some panes of glass. The accident occurred entirely owing to the denseness of the fog and to the gross negligence of one driver running outside of his own schedule. Trusting you will give publicity to this correction,—I am, &c.,

December 24, 1891. W. S. GRAFF BAKER.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Offices not later than first post Thursday morning.*]

TENDERS INVITED.—The Manchester Corporation Gas Committee invite tenders for the supply of engines and boilers for the central electric light station in Dickinson-street. Conditions of contract and specifications may be obtained on application to Mr. C. Nickson, superintendent of the Gas Department, Town Hall; and tenders, addressed to the Chairman of the Gas Committee, are to be delivered at the Gas Offices, Town Hall, on or before January 20th. Further particulars will be found in our advertisement columns.

——— It will also be seen by our advertisement columns that the Chiswick Local Board are prepared to receive tenders for providing and fixing 10 alarm posts, and 16 calls to fireman, &c., and the necessary instruments in connection therewith, at the Fire Station in the High-road, Chiswick. Plans can be seen, and information obtained, of Mr. Arthur Ramsden, engineer and surveyor, Vestry Hall, Chiswick; and tenders are to be delivered to the Chairman, at a meeting of the Board to be held on January 6th, at 8 p.m., at the Vestry Hall.

TENDERS RECEIVED.—The Chatham, Rochester and District Electric Lighting Company (Limited) have received the following tenders for the erection of engine-room and other works at Chatham:—W. C. Snow, New Brompton, £1,300; W. Hocking, Strood, £1,240; G. Batchelor, Strood, £1,237.

Digitized by Google

MESSRS. PATERSON AND COOPER.—This firm inform us they have been very busy during the whole of the past year, and in particular during the latter part. Shiplighting has contributed largely to the volume of business, and amongst the contracts on hand are those for the Allan line, the General Steam Navigation Company, and the Clyde Shipping Company. Dynamos during the past year have averaged a much larger size than previously. The arc lamp department has been busy, and large numbers have been sold for use. On alternating and constant current circuits a large number of important installations have been erected by Messrs. Paterson and Cooper, and the firm have still several important contracts on hand, including the lighting of the *Daily Chronicle* and *Lloyd's Newspaper* offices in Fleet-street, and the stores and wharf of Messrs. Nelson and Co., Lambeth.

MESSRS. J. H. HOLMES AND CO.—The *employés* of this firm held their fourth annual dinner last Saturday at the Crown Hotel, Newcastle-on-Tyne. The party numbered fifty, and after dinner an enjoyable programme was gone through. In response to the toast of "The Firm," Mr. J. H. Holmes gave a very interesting account of the evolution of the business of J. H. Holmes and Co., which was established in 1883, and made its first dynamo in 1885, and have recently heard that it is still working very well. The first ship lighted on the Tyne was lighted by Messrs. Holmes and Co. At the present time over 500 dynamos are at work, and the 624th machine is now being built. The toast of "The Electrical Engineers" was responded to by Mr. Broadbent, who gave a brief summary of the year's work, and remarked that during the year the firm had completed over 90 installations, and had fixed over 11,500 lamps; 95 dynamos had been erected for these installations. The year's output of dynamos had been 125.

EXETER ELECTRIC LIGHT COMPANY (LIMITED).—This Company have purchased the business and stock of the Exeter branch of the Italian Art Fittings Company, and have removed the latter to their new show rooms, 82, Fore-street, Exeter, where they intend to keep a large selection of electrical fittings.

BUSINESS FOR DISPOSAL.—There is for disposal in Russia an old-established electrical engineering business, brief particulars of which will be found in our advertising columns.

CHANGE OF ADDRESS.—Messrs. Barnes and Low, electrical engineers, notify us that on and after December 31, 1891, their business will be carried on at their new premises, No. 8, Exhibition-road, South Kensington.

MESSRS. GEORGE BOOR AND CO.—This firm, of 1 and 2, Artillery-lane, Bishopsgate-street, London, E.C., have been appointed by Messrs. Thompson and Robertson, of New York, sole agents for Europe and the Colonies for their new fibrous dry batteries.

DISASTROUS FIRE.—An extensive fire broke out on Christmas Day at the glass works of Messrs. Dan Rylands and Co. (Limited), the makers of the well-known glass-lined tubing, at Stairfoot, near Barnsley, by which damage was done to the amount of £60,000.

TRADE CATALOGUES.—We have received from Messrs. Dorman and Smith a catalogue and price list of their well-known electrical apparatus, including lamp holders, switches, cut-outs, switchboards, ceiling roses, brackets, and general electric light fittings.

——— Mr. Ronald A. Scott sends us a copy of his sheet price list for 1892, of the dynamos, motors, projectors, &c., made by him.

ALMANACS.—The Direct United States Cable Company send us a useful block almanac with space for memoranda, &c.

——— Messrs. Crompton and Co. send us a blotting pad and diary, similar to that issued last year, and which, with other similar pads, we have found very useful.

——— The Electrical Power Storage Company provide a most useful combination blotting pad, calendar, diary, and indexed memorandum, together with a full illustrated catalogue of their batteries and other goods.

——— Messrs. Fletcher and Co., of Warrington, send a block almanac with illustrations of their numerous gas appliances.

——— Messrs. W. H. Willcox and Co. send us a sheet date-remembrancer for 1892, each sheet showing illustrations of the very various manufactures of the firm.

BOOKS, &c., RECEIVED.

"Electricity Up to Date." By John B. Verity. (London: Frederick Warne and Co. 1s. 6d.)

"Yorkshire College, Leeds. Prospectus of Day Classes."

"How to Make Inventions." By E. P. Thompson. (New York: D. Van Nostrand. London Kegan, Paul and Co.)

"Decorative Electricity." By Mrs. J. E. H. Gordon. Second Edition. (London: Sampson Low and Co.)

COMPANIES' MEETINGS & REPORTS.

Phonopore Syndicate (Limited).

The third annual general meeting of the Phonopore Syndicate (Limited), was held at Winchester House, E.C., on Monday last; Mr. E. H. Pollard presiding.

The SECRETARY (Mr. Percy Andreae) having read the notice convening the meeting,

The CHAIRMAN referred to the suggestion made in the report to the shareholders that, in view of certain important negotiotions now in progress, not only for the introduction of the phonopore telegraph on working lines, but also for the disposal of a portion of the Syndicate's patent rights, the meeting should be of a formal character only, and that all discussion of the Syndicate's affairs should be avoided. He was sure it would be in the interest of all the shareholders that, pending these negotiations, which he believed they would consider most satisfactory, no public allusion to their exact position and prospects should be made. This was the suggestion of the Committee, which the meeting could adopt or decline as it thought fit. The Committee had nothing to conceal, and if any shareholder wished for detailed information, and would call upon the Secretary, he would afford it. Reviewing the business of the past year, he pointed out that, in spite of the fact that the Committee had not been in a position to supply instruments for the actual working services of telegraph administrations until the middle of June, the phonopore telegraph apparatus had, since that time, been supplied to a very large number of the telegraph administrations of Governments and railways in all parts of the world. This was a fact for which the Committee took credit. But what was far more gratifying was that, after every possible practical test had been applied to the system that electrical ingenuity and science could devise, its successful employment had now been placed beyond a doubt. In substantiation of this statement he need only refer them to the report of Mr. Latimer Clark on the working of the phonopore telegraph in the service of the Midland and Great Northern Railway Companies—a report which, it was satisfactory to know, had since been fully confirmed by the official testimony of these and other telegraph administrations which were employing the phonopore telegraph. He concluded by moving the adoption of the report and the acceptance of the accounts.

Mr. G. N. DAWE seconded the proposal, and asked the Chairman what was the cause of the delay in receiving the instruments for commercial use.

The CHAIRMAN said that at the time of the last report they expected that their order for the manufacture of the instruments would be executed within six weeks from the date of its issue. The order was given in February, but from various causes the instruments were not delivered until June.

Mr. MOCATTA said it was important also that they should be most careful at the present moment, because they knew that whatever amount of money was required for what was now becoming a valuable commercial undertaking would be found, as the Company was in the hands of men who had the true interests of the shareholders at heart.

The motion that the report and accounts submitted by the Committee be adopted and passed was then put and carried unanimously.

Mr. Browne and Mr. E. H. Pollard, the retiring Directors, were then re-elected, as were also Messrs. Boyce and Ramsay, the accountants.

The CHAIRMAN said he presumed he might take it that it was their wish that the suggestion of the Committee—to confine the discussion at that meeting to mere matters of form, and to take the adjournment—should be complied with. He therefore proposed that the meeting be adjourned until April 22, 1892, unless the Committee should find it expedient to summon the shareholders together at an earlier date.

The motion for the adjournment was then put and carried; and the CHAIRMAN and Mr. BROWNE having briefly returned thanks for their re-election, the meeting terminated with the usual vote of thanks.

Elmore's Patent Copper Depositing Company (Limited).

The second annual ordinary general meeting of the shareholders of this Company was held on Wednesday at the Cannon-street Hotel, under the presidency of Mr. J. Jepson Atkinson.

The SECRETARY (Mr. J. Shurmer) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, there is an old saying, "Good wine needs no bush," and I think that after the report we have been able to send you, you will not think it necessary for me to address you at any great length. You will see by the report that all the preliminary difficulties have been entirely overcome, and that we are now ready to go forward and earn money for you, and pay you handsome dividends. When we double, treble, and even quadruple our present plant, which we shall in due course have to do, those dividends will be so increased that I honestly believe you will have a chance of getting returns of cent. per cent. upon your investment in the capital of the Company. You will be glad to hear that our difficulty is not to take orders, but to know what orders to refuse out of the great number on offer. As you know, there is a French Elmore Company formed to work the process in France, and last week I had the honour of being invited to see their work. These works are now in operation, and though designed for an output of 90 tons a week, already their manager reports that he can sell double their proposed output. From these remarks, and the figures which Mr. Elmore will give you, you will see there is not

Digitized by Google

the slightest question about our getting a sufficiency of orders. I have no dividend to declare, but I can state to you, gentlemen, that we are to-day actually earning a considerable one—there is £500 profit in our tanks for this week—and I myself expect that before very long we shall be able to send each of you a nice little cheque as the result of what we are earning. I should like to say a few words about our investment in land referred to in the report. As you are aware, we are not a Land Company, and in the ordinary course we should only have bought sufficient land for our own immediate requirements; but being myself an adjacent landowner, and knowing well its value in the neighbourhood of the rising town of Leeds, and finding that we should have to pay something like £2,000 an acre for any extension of our works, and then be exposed later on, if we wished to further increase them, to still larger demands, I strongly urged the Board to make the purchase of the whole estate at Haigh Park. This the Company did not see its way to do at the time, and Mr. William Elmore very pluckily stepped in and bought the property. Later on, when the land had increased in value, and we saw the bargain that Mr. Elmore had, we readily accepted his generous offer to let the Company take over the purchase at the original price. Since that time, as we have mentioned, the value of the land has greatly increased, and I have received a letter from a gentleman who is acknowledged in Leeds to be the greatest authority on the value of land in that neighbourhood, in which he says, "I think the Company have done well to acquire the estate, and especially if they can afford to wait awhile before realising." In addition to this and the other advantages set out in the report, the Midland Railway Company have not only agreed to spend a considerable sum in improving the means of communication with the estate, but have also arranged, later on, to build a passenger station contiguous to our property. In justice to Mr. Elmore I must say that he has worked like a Trojan, and, even if he has been slow in getting our Company to its present prosperous position, he has, nevertheless, given one of the greatest possible proofs of his zeal for the Company, and his interest therein, by giving up his purchase precisely on the same terms as he had procured it. If he had been a stranger, there would have been nothing wrong in his asking £25,000 profit on the price, and then we should have had a bargain. In fact, if at the end of a year or two the Company do not find that they have made a splended bargain, I shall be glad to take it off their hands. I think, therefore, that our thanks are very much due to Mr Elmore for the excellent position he has put us into in that respect; and I have no doubt that, before we part, you will favour him with a vote of thanks instead of a cheque for the profit he might otherwise have made. Three members of the Board retire. Sir John Morris is not allowed by his physician to offer himself for re-election, but possibly he may be able to join us again later on. With regard to the other two members, Mr. Carson and myself, I may say that Mr. Carson, from his knowledge as a Director of the Cape Copper Company, of which he was originally the manager, has been of great assistance, and is one of the four largest holders of our shares. I myself have every confidence in the great value of this invention, and I have had ever since it was only an idea in the mind of the inventor. I hold over 8,000 shares in the Company, and have upwards of £40,000 in the various Elmore Companies, and have never sold a single share, even when they were at £8 each, which figure, I believe, they will soon be at again. On the contrary, I have been steadily increasing my holding. In fact, I may say the Directors of your Company are by far the largest holders in the Company, holding I believe nearly a third of the issued capital. Mr. Elmore has addressed a statement to the Directors, dated December 28, 1891, in which he says, among many other things, that he confirms his report of the 30th November last, and the gratifying results he was then able to foreshadow, and begs to state that their experience since more than bears out his figures. He concludes his report as follows:—"In this report of to-day I have confined myself to what has actually been done and proved, and I consider it unnecessary to refer to the fact that our process is equally applicable to the deposition of other metals, and the manufacture of heavy ordnance, of a quality hitherto unknown, and I think you will find, as in the past, that every statement ever made by me as to the various applications of the process will be as fully borne out as those regarding the turn out of copper tubes and such like articles; this I have been able to prove to you to-day. In conclusion, the Chairman said I now beg to move—

"That the report and statement of accounts for the year ending June 30th last be passed and adopted."

General FIFE (a shareholder) seconded the motion.

A discussion followed, in which Messrs. Bogle, Pilcher, and other gentlemen took part, and

Mr. ELMORE, in reply, said that the accounts were made up to the 30th June. At that time they were making very little copper from their tanks, and consequently there was no profit, or very little profit, shown in the statement of accounts. The profits had all been made since. At the present time they were turning out a large quantity of copper tubes. With respect to the laminated tubes, at the commencement of their operations they started, unfortunately, with a very defective engine which, however, was made by one of the best engineering firms in the world, or supposed to be one of the best. It gave them considerable trouble, and was constantly breaking down. This was the cause of the laminated tubes, a few of which were sent out in the early period of the Company. The process was essentially a continuous one, and the stoppage of an engine for any time would cause a film of dust to settle on the solution in such a way as to cause a lamination. This, however, was a thing of the past, and never happened now. In the last six weeks they had sent out a very large quantity of tubes to some of the best firms in the world, who had not only expressed their high satisfaction with the quality of the tubes, but had repeated their orders. One Manchester firm had promised them an order for 1,000 tubes of 22 in. diameter, to be delivered over the next year. They had been exceedingly anxious not to send out any tubes for steam purposes lately, until, in fact, they were quite certain of their ground; and for this purpose he desired a little time ago that official tests should be made by the engineers and experts of the Board of Trade, the Admiralty, and Lloyds. Those bodies had consented to make these tests.

Mr. PILCHER asked if they would guarantee the tubes they now sent out, and

Mr. ELMORE replied that they would do so with pleasure. By the operation of the process, if the current was continuous and the rotation of the mandril in the tank was continuous the tubes must be of absolutely uniform strength throughout, and could not be laminated. There was no difficulty whatever in keeping the current continuous. These difficulties sometimes came as blessings in disguise. The very fact of their making a laminated tube actually caused the taking out of certain patents by the Company for the manufacture of sheet copper, which they were now making of magnificent quality. It was done automatically. It was not necessary to put the sheets through any rolling processs whatever, and the stuff was never touched by hand. They could, if necessary, sell it at a price decidedly below the ordinary market quotation. There was no doubt at all that if coppersmiths could procure a tube which would stand three times the pressure of another tube, they would be satisfied to give, at any rate, a little higher price; nevertheless, if necessary, they could sell it at less than the market price. With regard to the question as to their making a profit of £174,000 a year, he had never made such a statement, and he did not know to what it referred. Their working of 20 tons a week had only just commenced—within the last fortnight. He hoped that they would be able to get a considerable increase to their plant, and, in fact, be able to double it within three months.

The resolution was carried unanimously; and resolutions were afterwards passed re-electing the retiring Directors, Mr. Atkinson and Mr. Carson, and the auditors, Messrs. Price, Waterhouse, and Co.

Cordial votes of thanks to Mr. Elmore and his staff and to the Chairman and Directors were passed, and were acknowledged by Mr. Elmore and the Chairman; and the proceedings then terminated.

Elmore's Wire Manufacturing Company (Limited).

The first annual ordinary general meeting of the shareholders of the above Company was held on Wednesday last, at the Cannon-street Hotel; Mr. J. Jepson Atkinson presiding.

The SECRETARY (Mr. J. Shurmer) read the notice convening the meeting; and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: Gentlemen, the report speaks for itself, and is so exceedingly simple that in addressing you I can have very little to say. What will strike you first is that a Company calling itself a wire manufacturing Company should propose to you, its shareholders, after you have subscribed your capital, not even to put down plant to draw wire at all. This admits of an easy explanation. Gentlemen connected with the wire-drawing trade, and having large capital invested in drawing plant, approached us some time previous to your last general meeting, and having thoroughly tested the quality of the copper to be produced by us, offered to take our entire output at a price which, while satisfying us, did not interfere with their own business of drawing. Your Directors considered that this arrangement was better than entering into competition with the whole trade. This was explained to you at the last general meeting. Since then we have ascertained the fact that by depositing our large copper tube up to about a quarter of an inch and over, and then cutting them up into a wide spiral of, say, two inches, which can be done very easily indeed, we have a form of copper-ribbon or tape used for electric lighting and transmission of power. While the demand for this copper-tape exceeds our entire output the price is much in excess of the best price we could obtain for wire spirals such as the wire-drawers would have taken, so that even before the whole of our works are complete we shall have a better market for our produce than was contemplated when the prospectus was issued. The electric lighting of a town like Leeds would keep us busy for a length of time, and I am informed that for the electric lighting of London alone over 100,000 tons of this kind of strip will be used. A second very simple invention is likely to form an important source of revenue to us. It was found that by exposing the mandrel to the oxidizing action of the atmosphere for a few minutes, when a certain thickness of copper was deposited upon it, and then continuing the operation till a similar thickness of copper was deposited, and by a continual repetition of this process, a series of tubes could be formed entirely separate and distinct from one another. One cut down the length of these superimposed tubes gave, when opened out, a number of beautifully burnished sheets of perfectly even surface and thickness, and equal in every way to those known in the trade as planished sheet. These, of the size furnished by us, cannot be procured at the present time in the market, and consequently they will command a high price. All I have to say in addition is that this meeting was put off to the last minute in the hope that I should be able to announce to you that the 35-ton plant was at work; the fog and the Christmas holidays have prevented it, but there is steam in our boilers, and very little more to do at the plant, and we hope within three weeks or so to be at work. Our business being a mere repetition of the same process over and over again, and the fact that we have no customers to seek, or market to create, make it evident that as soon as ever we get a start our dividend-earning will commence. Some of you have seen the works, and know from what you have seen that a great deal has been done, and the drawing, accompanying the report, will give those who have not been down an idea of the size of our premises, which, I am told, comprise the largest shed in Yorkshire. He concluded by moving the adoption of the report and accounts.

Mr. E. J. CARSON seconded the motion.

Digitized by Google

The MANAGING DIRECTOR (Mr. Wm. Elmore) explained that owing to the delay of the various contractors responsible for providing the necessary plant, &c., in fulfilling their contracts, the Company had not been able up to date, as had been expected, to proceed with its operations; but he expected that within a fortnight from this time it would be in a position to produce about 35 tons of copper wire per week, which could be readily increased, with little additional expenditure, to 70 tons per week.

The motion was agreed to.

Mr. BLOOMER proposed and Mr. WHITE seconded the re-appointment of the auditors, Messrs. Deloitte, Dever, Griffiths, and Co.

The resolution was carried unanimously.

On the motion of Mr. GUARRACEM, seconded by a SHAREHOLDER, a vote of thanks was unanimously accorded to Mr. Elmore for his services to the Company.

Mr. ELMORE, in expressing his acknowledgments, assured the shareholders that no effort on his part would be spared to make the business in which the Company had embarked a financial success.

A vote of thanks having been passed to the Chairman and Directors, the proceedings terminated.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELSNER AND CO. (LIMITED).—This Company was registered on December 22, 1891, with a capital of £12,000, in £50 shares, by Messrs. Foss and Ledsam, 3, Abchurch-lane, London, E.C. The objects are to acquire and carry on the business of engineers in all its branches, and manufacturers of machinery, plant, and goods of all descriptions, and to act as merchants, contractors, and commission agents for the purchase and sale of all kinds of plant, machinery, chemicals, and other processes and merchandise. Registered office: 80, Lombard-street, London, E.C.

HULL TRAMWAYS COMPANY (LIMITED).—This Company was registered on December 23, 1891, with a capital of £25,000, divided into 2,500 Founders' shares of £1 each, and 2,250 ordinary shares of £10 each, by Walter Webb and Co., of 23, Queen Victoria-street, London, E.C. The objects are to purchase or otherwise acquire, or take a lease of, all or parts of the existing street tramways at or in the neighbourhood of Kingston-upon-Hull, and to equip, maintain, and work with horse, steam, or other mechanical power, or electricity, the tramways belonging to or leased by the Company.

KEIGHLEY ELECTRICAL ENGINEERING COMPANY (LIMITED).—This Company was registered on December 24, 1891, with a capital of £10,000, in £1 shares, by Ullathorne, Currey, and Villiers, 1, Field-court, Gray's Inn, W.C. The objects are to carry on in England and elsewhere the business of electrical engineers and of electric lighting, and to produce and supply electricity or electrical currents and force; and also to supply whole or in part, by means of electricity or electrical currents or force, light, heat, motive-power or force, or telegraphic, telephonic, or other means of communication or illumination, and to acquire the business of C. J. Garnett, now carried on by him at South-street, Keighley, and to carry on the same. Registered without Articles of Association.

LIVERPOOL METAL AND HARDWARE COMPANY (LIMITED).—This Company was registered on December 22, 1891, with a capital of £12,000, in £10 shares, by J. and R. Gole, 4, Lime-street, London, E.C. The objects are to acquire the undertaking of Peter Connor, McIntyre, and Co. (Limited), carried on at Hanover-street, Liverpool, and elsewhere; to carry on the business of copper, brass, iron, lead, tin, zinc, spelter and general metal and hardware merchants, and also that of mechanical and electrical engineers, machinists, smiths, woodworkers, &c.

MINERAL SYNDICATE OF SMYRNA (LIMITED).—This Company was registered on December 24, 1891, with a capital of £15,000, in £5 shares, by Batten, Proffitt, and Scott, 32, Great George-street, Westminster, London, S.W. The objects are to carry on and conduct in England, Turkey, and elsewhere the business of manufacturers of emery flux, ferro aluminium, copper, and aluminium, ironmasters, colliery proprietors, chemical manufacturers, engineers, smelters, steel makers, and iron founders, and to construct, carry out, maintain, and work (*inter alia*) gas works, hydraulic works, electric light, heat, and power supply works, chemical works, &c.

AUTOMATIC STANDARD SCREW COMPANY (LIMITED).—A resolution was passed at a meeting held on November 26th, and confirmed at a meeting held on December 14th, that the Company be voluntarily wound up, and that Mr. H. L. Roth, Lightcliffe, be liquidator.

BIRMINGHAM TELEGRAPH FACTORY (LIMITED).—An agreement made November 25, 1890 (and filed on December 24, 1891), between Fowler, Lancaster, and Co. (Limited), electrical engineers (herein called the vendors) of the one part, and A. F. Hoggins (called the purchaser), agent on behalf of the above-named Company, then in formation, of the other part, states that whereas the vendors have for some time past carried on the business of electric telegraph instruments, bell and battery manufacturers, in connection with, or as a department of, their business of general electrical engineers, manufacturers, and contractors in their factory, Albert Works, Graham-street, Birmingham, it is therefore agreed that the vendors shall sell and the purchaser shall buy (1) the goodwill of the said department of their business of electric telegraph and telephone and other electric signalling apparatus or instruments, bell, and battery manufacturers; (2) all the stock-in-trade connected with such business; (3) all unfinished contracts, agreements, rights, and privileges to which the vendors are or may be entitled in relation to the said department; and (4) all patents or licenses connected therewith, provided that the purchaser shall not be compelled to take over with the conveyance hereby contemplated all rights and liabilities under the agreement with Mason and Avery, being a licence for the manufacture of Snelgrove's electric bells. The consideration for the said sale shall be £5,000, to be satisfied by the payment of £1,000 in cash, and by the allotment of 400 fully paid-up shares in the Company of £10 each, to be numbered 781 to 1,180 inclusive. An agreement dated December 15, 1891 (also filed on December 24th) between Fowler Lancaster and Company (Limited) of the one part, A. F. Hoggins of the second part, and the Birmingham Telegraph Factory (Limited), of the third part, states that it is mutually agreed that the above agreement is hereby adopted by the Company, and shall be binding on the Company, and the said A. F. Hoggins shall from henceforth be discharged from all liabilities under or in respect of the said agreement The above named Company was registered on December 31, 1890, with a capital of £50,000, in £10 shares, to carry on the business of telegraph and telephone engineers and contractors, and manufacturers of telegraph appliances, telephone appliances, wires, cables, insulated materials, and other apparatus, and it is intended to acquire the business carried on by Joseph Slater Lewis, telegraph engineer and manufacturer, at Birmingham. The statutory return made up to May 6, 1891, and filed on the 14th following, shows that only seven shares had been taken up, on which nothing had been called or paid. Registered office: Birmingham Telegraph Factory, Graham-street, Birmingham.

ELECTRIC INSTALLATION AND MAINTENANCE COMPANY (LIMITED).—At an extraordinary general meeting of the members of the above-named Company, duly convened, and held at the registered offices, 4, Great Winchester-street, London, E.C., on December 3, 1891, the following special resolutions (see *The Electrician*, December 4th, p. 133) were duly passed, and at a subsequent extraordinary general meeting of the members of the said Company, also duly convened and held at the same place, on December 19, 1891, the following special resolutions were duly confirmed: —(1) "That the name of the Company be changed from the 'Electric Installation and Maintenance Company (Limited)' to the 'Crystal Palace District Electric Supply Company (Limited)';" (2) "That each of the existing £10 shares be divided into ten £1 shares"; (3) "That the existing Articles of Association of the Company be cancelled, and that the Articles of Association, which have been produced to the meeting and signed by the Chairman, be the regulations of the Company, and be registered accordingly." The new Articles of Association of the above-named Company, which were registered on December 23, 1891, with the foregoing show that the capital is now £100,000, divided into 100,000 shares of £1 each. The number of Directors shall not be less than three nor more than seven, but the continuing Directors may act notwithstanding any number of vacancies. The present Directors, viz., Colonel Lewis Vivian Loyd, D.L., Joseph Pyke, Esq., Samuel Green, Esq., and Robert M. Meyer, Esq., shall hold office until the first ordinary general meeting in 1894. Qualification, shares to the nominal amount of £250. Remuneration, £1,000 per annum (in addition to their travelling expenses, and also in addition to the salary of a managing Director or Directors, if any), and in any year when a dividend of 6 per cent has been earned for the ordinary shareholders, the Directors shall be entitled by way of extra remuneration to a further sum of £5 per cent. per annum on all additional profits, the above to be divisible among the Directors as they themselves determine. The above Company was registered on June 30, 1883, under the title of the "Electric Construction and Maintenance Company (Limited)," with a capital of £100,000, in £10 shares. The annual returns for the years 1884, 1885, 1886, 1887, and 1888, which were all filed on June 27, 1889, show that only seven shares had been taken up, and nothing had been called or paid. The return for 1889, however, shows that 82 shares had been taken up, but nothing had been called or paid. The additional 75 shares were taken by H. G. Wright, Esq., John Irving Courtenay, Esq., and Sir Henry C. Mance, who took 25 shares each. In November, 1889, the name of the Company was changed to "The Electric Installation and Maintenance Company (Limited)," and the license of the Board of Trade for such change granted December 9, 1889. The return for 1890, filed the 27th February last, shows that 626 shares have been taken up, £5 per share called upon 487 of these, and £2,260 paid, leaving £175 in arrears. £1,390 is considered as paid on 139 shares, and, in addition to the shares issued, agreements had been entered into for appropriating under Provisional Orders, obtained or applied for, 5,724 shares of £10 each fully paid. The shareholders include the well-known names of J. Irving Courtenay, Esq. (25 shares), Sir H. C. Mance (25), J. B. Verity, Esq. (50), Sir Daniel Cooper, Bart., G.C.M.G. (50), James Pender, Esq. (50), and Sir C. D. Fox (50), and the Electric Construction Corporation (Limited) hold the 139 fully-paid shares. Present registered office: 4, Great Winchester-street, London, E.C.

LIVERPOOL ELECTRIC SUPPLY COMPANY (LIMITED).—The following was filed on December 24, 1891:—At extraordinary general meetings of the Liverpool Electric Supply Company (Limited), duly convened and held respectively on December 7 and 23, 1891, the subjoined special resolutions were duly passed and confirmed: (1.) That in accordance with Section 9 of the Liverpool Electric Lighting Order, 1889, further share capital of the Company of the nominal value of £40,000 be, and the same is hereby, appropriated as a separate capital for the purpose of the undertaking thereby authorised in respect of the district comprised in schedule A of the said Order. (2.) That in accordance with Section C of the Liverpool Electric Lighting Order, 1891, share capital of the Company of the nominal value of £20,000 be, and the same is hereby, appropriated as a separate capital for the purpose of the undertaking authorised by that Order. (3.) That the regulations contained in the printed document submitted to the meeting, and for the purpose of identification subscribed by the Chairman thereof, be, and the same is hereby approved, and that such regula-

Digitized by Google

tions be, and they are hereby, adopted as the regulations of the Company, to the exclusion of all the existing regulations thereof. The new Articles of Association, which were filed with the above notice, state that the number of Directors shall not be less than three nor more than nine, the present Directors being J. S. H. Banner, A. H. Holme, S. H. Holme, Sir David Radcliffe, T. von Sobbé, J. C. Vaudrey, and Domingo de Ybarrondo. Qualification, £500. Remuneration as determined by the Company in general meeting. The above Company was registered on January 10, 1883, with a capital of £10,000, in £5 shares, and in July, 1885, the capital of the Company was raised to £200,000 by the addition thereto of 38,000 shares of £5 each. The last return, made up to March 10, 1891, and filed on April 7, 1891, shows that all the shares have been taken up, and upon 10,000 the full amount has been called, while upon the remainder £3 per share has been called, resulting in the payment of £139,400. 10s., leaving £599. 10s. in arrears. Registered office: 15, Highfield-street, Liverpool.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts of this Company for the week ended December 27th amounted to £871, as against £785 for the corresponding period of last year, an increase of £86. Aggregate receipts for half-year to date, £19,221.

QUEEN ANNE'S MANSIONS LIGHTING AND HEATING COMPANY (LIMITED).—Notice is given that the coupons due January 1, 1892, on the debentures of the above Company will be paid at the National Provincial Bank of England (Limited), 112, Bishopsgate-street Within, on and after to-day. Coupons must be lodged three clear days for examination.

MANITOBA ELECTRIC AND GAS LIGHT COMPANY (LIMITED).—Messrs. Robert A. McLean and Co. announce that the coupons due January 1st on the Six per Cent. First Mortgage Bonds will be paid by them on and after to-day.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 712.—Vol. XXVIII. FRIDAY, JANUARY 8, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

For the first time in English history a peerage has been conferred solely for eminence in science. Sir William Thomson, as we must still call him, has already received all the honours that science can give; and as no mark of this kind can add to his fame, it is to the House of Lords and to the whole body of the scientific men of this country that we offer our congratulations. The Upper House has room for such men, and work for them to do; and while we have little fears as to its future, nothing can better conduce to its stability than the occasional selection of such men as Sir William Thomson to fill its seats. Upon science, on the other hand, an important dignity is conferred. The law is nothing if not dignified; and law lords, whether peers or no, are not uncommon. Successful tradesmen who have acquired political influence, as well as that accumulation of wealth which is considered to be the mark of success, are thus rewarded; while for mere politics the House of Lords is the natural goal of most men who succeed in that profession. Sir William Thomson has his heart in his work, and it need not be feared that he will waste his time in party politics.

The recently circulated memorandum to the President of the Board of Trade on the subject of overhead wires was put forth by the Electrical Trades' Section of the London Chamber of Commerce, under the impression that the Board of Trade had "addressed several firms engaged in electric contract work, informing them that overhead wires will in no case be allowed as a permanency." Assuming this to be correct, we commented upon "Overhead Wires and their Wardens" in a leading article four weeks ago. But question afterwards arose as to the accuracy of this assumption; and soon afterwards we learned, upon the best authority, that the Board of Trade had not made, and were not intending to make, any such drastic regulation. We left the matter in the hope that the memorandum would be backed by a sufficient number of signatures to draw from the Board of Trade a definite pronouncement on this point. No such pronouncement has, so far as we are aware, appeared; but a perfectly satisfactory solution to any doubts that may have remained is to be found in the following letter:—

[Copy.]

Board of Trade (Railway Department), London, S.W.,
4th January, 1892.

Gentlemen,—With reference to the letter addressed by your firm to the President of the Board of Trade, urging that this Department should not lay down as a settled principle that no overhead conductors for the supply of electric energy should be allowed, but that in rural districts at least the circumstances of each particular case should determine whether overhead work should or should not be sanctioned, I am directed by the Board of Trade to say that your letter appears to have been written under a misapprehension of the practice of this Department.

The Board of Trade are of opinion that, as a general rule, the use of overhead wires is accompanied by many disadvantages, both as regards the safety of the public and the efficiency of the supply of energy; and they think it is most desirable that mains for the supply of energy under Provisional Orders or Licenses should, wherever practicable, be placed under ground.

They have not, however, laid down any absolute rule that overhead wires shall in no case be employed; and while they have declined, in the absence of any special circumstances, to approve of a system in which the use of such wires was contemplated as a permanent arrangement in the central and populous portions of a town, they have, on various occasions where the circumstances appeared to justify it and the local authorities approved, authorised the employment of overhead wires in rural districts or the outlying and less populous portions of towns.

The Board of Trade see no reason to depart from the practice they have hitherto adopted of considering each application for permission to use overhead wires on its merits, having regard to the special circumstances of the district, and they will be prepared to authorise the use of such wires in any case in which they are satisfied that the interests of the public require it.—I am, Gentlemen, your obedient servant,

(Signed) HENRY G. CALCRAFT.

Some six months ago we had occasion to allude to the Parsons Steam Turbine, and observed that it was an ingenious motor which was doubtless excellently adapted for certain purposes, but that no satisfactory information on its economy had been published. These remarks, together with a misunderstanding on another matter, caused, to our great regret, some annoyance. The misunderstanding was remedied at once; and by the publication, in full, in the present issue of a report on trials conducted by Prof. Ewing, we are enabled to dismiss our doubts as to steam consumption which we held in common with many engineers, and to congratulate Mr. Parsons upon the extremely satisfactory results which have been attained. In answer to our inquiries Prof. Ewing informs us that the coils of wire on which the load was spent were single spirals, very openly wound, and were run at a high temperature, and he assumes that the correction for lag must have been unimportant. Errors due to induction would certainly be small compared with the losses which must arise from other causes to which Prof. Ewing alludes. Surprising as the figure 27·6 lbs. of steam per E.H.P. per hour will be to our readers, the consumption at three-quarter and at half loads is still more remarkable. The fact that the law connecting rate of consumption with the load is of this nature dispels the idea that this turbine is a windmill, and permits

Digitized by Google

it to rank as a steam engine; and, as far as the present information goes, a very good one.

THE analogy that the flow of electricity bears to a current of water is so good that everyone uses it. It forms the only possible mode of describing in a simple manner the chief facts of electricity. When magnetism has to be accounted for, the analogy, however, altogether fails; and its continual use is only justifiable because, in spite of its want of completeness, it is the only clear way of regarding any large part of the phenomena of electricity and magnetism. To strain the analogy too far by seeking out analogues where no exact ones exist is, however, undesirable. Mr. MADDEN'S letter this week, by comparing a quantity of electricity with a mass of water, certainly points out a good analogue, but this end is only attained by comparing voltage with the product of a length into g, the constant of gravitation; and such a comparison is anything but satisfactory. Let analogies be retained by all means for elementary teaching, as in Mr. H. E. HARRISON'S articles; and let them be pushed occasionally, just to see where they fail, and thus to avoid misuse of them. If Mr. MADDEN had suggested that his re-arrangement made the analogy *better*, and not that it made it *exact*, it would have been more in accordance with the postscript to his letter. We hold the breakdown of this analogy to be in one sense a matter of some importance, since it tends to support our contention, that the notion of a coulomb which implies a quantity of electricity having a substantial existence is completely fallacious, and has arisen from the use of the word "current" as signifying a flow of something.

A DISCUSSION, fruitless as usual, has been carried on in the columns of the *Financial News* as to the cost of electric lighting. It was opened by a rather commonplace leading article; and a Mr. HARSTON, on whom the blessings of the supply provided by the House-to-House Company appear to be thrown away, began the correspondence by a statement of the alarming annual cost of electric lighting and the inefficiency of glow-lamps compared with gas burners. Mr. CROMPTON replied; and, forgetting for the moment that he was addressing a prejudiced audience, adopted the term "sheer cost" of production, which was used by the *Financial News* to express what our readers will readily understand to be current engine-room expenses, as distinguished from maintenance and administrative charges. But when Mr. HARSTON displayed his lack of acquaintance with the matter by supposing that Mr. CROMPTON was connected with the House-to-House Company, the latter, remembering the memorable battle of battery transformers *versus* alternate-current transformers in which he played so prominent a part, and mindful, no doubt, of the numerous points of engineering detail on which he holds diametrically opposite views to those of the advisers of the Brompton Station, to say nothing of half-forgotten opposition and emulation when the younger Company was founded, naturally replied, "Far from this being the case, instead of being connected we are in all respects their rivals and competitors." He explained the rather loose expression "sheer cost," and went so far as to say that the cost to the consumer in the future will only "bear some relation to this 'sheer cost,'" and that this "bears but a small proportion to the total cost to the supply companies." He maintained that the "sheer cost" of producing electricity by the high-pressure system as at present employed by the House-to-House Company is considerably greater than by the low-pressure system. He gave £25 as the average annual electric lighting bill for large houses in Kensington, whereas gas bills in the same houses used to be £18 to £20, the annual cost for each light fixed being from 8s. to 9s. 6d.

THE other correspondent, ignoring Mr. CROMPTON'S explanation altogether, or being unable to understand it, continued the discussion by saying that the House-to-House Company charge 8d. per Board of Trade unit, which Mr. CROMPTON says can be produced for 2d. Even a gas engineer could hardly fall into such an error. A letter then followed from a "Mechanical Engineer and Specialist," who knows so little about the matter as to suggest that a competition should be held with ten ordinary street lamps, ten high-power street lamps, and one extra high-power lamp and a few "indoor lights," the installation to be complete in itself as to motive-power, &c., and to "embrace all plant, labour, and materials necessary for the work, without the aid of any extraneous assistance whatever." The "specialist" ignores Mr. CROMPTON'S statement that the present price is high, "owing to the comparatively limited use of electricity for lighting purposes." This comparatively limited use allows of only 3,000 indicated horse-power by the Kensington and Knightsbridge Company, and yet we have a "Mechanical Engineer and Specialist," writing about "a challenge," "a penalty worth naming—say £500," and so on, for a "test" with 12 H.P. or so.

ON Monday this absurd correspondence was supplemented by a letter from Mr. GAY, the manager of the House-to-House Company. He is surprised that Mr. CROMPTON considers himself to be "a rival and competitor to the House-to-House Company, because the House-to-House Company hold sole parliamentary rights in a portion of Kensington." He goes on to misrepresent Mr. CROMPTON'S statement about the comparative cost of producing high-pressure and low-pressure electric supply, and supports his misconception by the allegation that "almost all the London Companies are charging the same price as the House-to-House Company, viz., 8d. per unit," forgetting the Metropolitan, St. James and Pall Mall, London Electricity Supply Companies, and St. Pancras, to say nothing of special contracts with the Westminster Company. Mr. GAY gives an elaborate analysis of his idea of the cost of an article, but does not give a single figure to compare with Mr. CROMPTON'S 2d. In his opinion the use of "sheer cost" "is a very erroneous way of treating the question of the cost of electricity."

A REPORT by Mr. PREECE on an electrolytic process passed through our hands a day or two ago, in which the well recognised quantity which Mr. CROMPTON calls "sheer cost"

Digitized by Google

was set at ½d. per unit. The idea follows naturally after the "load factor" which Mr. CROMPTON has taken some pains to define. It is that quantity which is directly proportional to the output, while salaries of managers, rent, interest, &c., remain practically constant. MR. CROMPTON expresses it in a slightly different way in a letter in yesterday's issue. "We think that by the words 'sheer cost' you very happily designate that portion of the cost which is peculiar to the two systems themselves, and not the ordinary expenses of business management which are common to the two systems."

IF on any occasion we discover that our readers have been wrongly informed upon any point in the numerous matters which are discussed in these columns, we never hesitate to make a speedy and full correction. It is unwise to make corrections in haste; the second source of information may be as untrustworthy as the first. But a criticism from our excellent contemporary the *Electrical Engineer* of New York on the subject of "The Microphone in America" commands attention, if only because its facilities for mastering the subject are obviously so much greater than our own. Those of our readers who are interested in American microphones or who have a taste for American Patent Law will be glad to learn the exact mode of procedure, and for their benefit we give the comments in full. We must leave experts to decide whether any ponderous joke underlies these remarks.

"KNOCKING OUT" THE BERLINER PATENT.

The picturesque misinformation that cultivated Englishmen possess about this country is strikingly exemplified in an able editorial on "The Microphone in America," appearing in the December 4 issue of *The Electrician*. Its view of the granting of the Berliner patent is thus expressed: "It is as if one had appropriated a wrong umbrella and after wearing it out taken it back again, getting a new one in its place. You cannot do that in polite society; *but you can in the New York Patent Office.*" Our contemporary adds that "there is talk of invoking *the aid of the Legislature* to put an end to collusive and injurious 'interferences.'" It is a pity that our contemporary, who is usually so well informed and so sound in judgment, should be under the impression that the "New York Patent Office" allows this sort of thing, or that the matter is subject to the tender mercies of our State Legislature. It is the Chicago Board of Trade that is responsible in such cases, and these collusive interferences can only be put an end to by the "referendum" in the District of Columbia, or by a constitutional ballot in the thirteen original States of the Union. No doubt this is a roundabout way of correcting an abuse, but it has been carefully modeled after the precedent which requires that the Parliament of the British Empire shall sit in judgment on the wish of Puddlecombe-by-the-Haystack to have a street railway.

Appointment.—Mr. Alfred Hay, B.Sc., has been appointed demonstrator of electrical engineering at the University College, Nottingham.

Frankfort Exhibition.—The receipts of this Exhibition amounted to £75,700 and the expenses to £68,100, leaving a profit of £7,600.

Mr. Cyrus Field.—The latest bulletin telegraphed is as follows:—"Mr. Field is still confined to the house, but is slowly improving."

Railway Alarm Signal.—Messrs. Shiels and Elliot's electric alarm-bell for passenger trains was tested experimentally on the North British Railway last week.

The Western and Brasilian Telegraph Company.—This Company notifies that direct communication by its cables with Monte Video and Buenos Ayres is now restored.

Telegraph Clerks' Agitation.—The reply of the Postmaster General to the two memorials recently sent in asking for better remuneration of clerks after a few' years service, in which he declines to reopen the matter, has created considerable disappointment.

Interurban Telephony.—The Bulgarian Government has recently connected Sofia and Philippopolis (100 miles) by a telephone trunk wire.—The Paris-Nantes telephone line (225 miles) came into operation on December 21st.—The telephone line between Prague and Reichenberg was opened to the public on the 20th of last month.—A telephone line is about to be constructed between Madrid and San Sebastian, a distance of over 300 miles.

Postal Telegraph Revenue.—In the revenue returns for the quarter ending December 31, 1891, the telegraph service receipts amount to £645,000, as against £615,000 for the corresponding period of 1890, the increase being £30,000, or 5 per cent. For the first three quarters of the current financial year the telegraph service receipts amount to £1,910,000, as against £1,840,000 for the three corresponding quarters of the preceding year. The increase in this case is £70,000, or 3·2 per cent.

The Johnston System of Conduits.—The Johnston conduit patents are said to have been acquired by an English syndicate, and will be brought before the public shortly. The Johnston conduit was described by Mr. J. B. Verity in his Paper on "Underground Conduits and Electrical Conductors," read before the Institution of Electrical Engineers on April 11, 1889 (*The Electrician*, Vol. XXII., p. 715). The conduit is of iron, and is made in 6ft. lengths, and has six ducts. It has been in use in New York.

Electrical Literature.—Messrs. Whittaker and Co. inform us that they have made arrangements with the editor of *El Telegrafista Español* for the translation into Spanish of Mr. Preece's work upon "The Telephone." The book has already been translated into both French and German. The same firm will publish shortly in a cheap form Mr. A. R. Bennett's Papers on the Telephoning of Great Cities, and the Electrical Parcel Exchange System, which attracted some attention at this year's British Association meeting.

Electricity v. Gas for Street Lighting.—"What we would suggest for 1892," says the *Gas World*, "is that the gas companies of the kingdom should combine for the purpose of giving a display of street lighting in some central part of the metropolis—a display that would not be confined to a square only, but to a square and a whole street, say Trafalgar-square and the Strand. Let this section be lit up in the best manner; and after the public has seen what gas can do, publish the cost, and ask the electricians to do the same."

The Imperial Ottoman Bank.—It was decided a short time ago to light the handsome new buildings which are in course of construction at Constantinople with the electric light, and tenders were invited from a few English firms. After considerable competition the order was eventually given to Messrs. Drake and Gorham. Soon afterwards, however, the order was cancelled by telegram, as the Sultan had refused to allow the work to proceed. It is rumoured that His Majesty understood the electricity was to be generated by "dynamite," and was therefore afraid of an explosion.

The Crompton-Howell Accumulator.—In the list of London Central Lighting Stations, which appeared on p. 232 of our last issue, the secondary batteries at the Westminster Company's stations were put down as of the E.P.S. instead of the Crompton-Howell type. This printer's error will not, however, mislead many of our readers, as we think it is generally known that Crompton-Howell batteries are employed at these stations, where we understand they are "working very well indeed," as well as at Notting Hill, Bradford, Liverpool, and Birmingham. An interesting report on this accumulator will be found in our correspondence columns.

St. Pancras Vestry.—The St. Pancras Vestry have deposited a Bill, which will be introduced into Parliament next Session,

Digitized by Google

under which powers are sought to raise £360,000 for the electric lighting of the whole of the parish, in addition to any sum that may be required for paying the costs of obtaining this Act. The period for the redemption of this loan is fixed at 42 years. The Vestry also seek power by this Bill to appropriate for electric lighting purposes the pneumatic tubes laid by the Pneumatic Despatch Company, but now abandoned, in Tottenham Court-road, Euston-road, Hampstead-road, and Drummond-street.

The Patent Office in 1891.—At the end of 1889 the applications for patents were 1,905 in excess of those sent in during 1888, this being the largest increase in any one year since the Act of 1883. At the close of 1890 there was an advance of only 299 as compared with the preceding twelve months. But during 1891 the total was 22,872, exceeding those of the previous year by 1,565. The financial position of the Patent Office is very good. The work of 1890 resulted in a surplus which exceeded £100,000; and as the operations of the office have since been conducted in a practically identical manner, there will be a still greater surplus arising from the business of 1891.

Accumulator Cars proposed for Glasgow.—In view of the termination of the Glasgow Tramway Company's lease with the Town Council, and the probable resolution of the Corporation to work the local tramway system as a municipal concern, the Tramways Committee have lately given their special consideration to the mode of traction which they should recommend the Town Council to authorise. So far as they have been able to formulate their views on the subject, they have come to a resolution in favour of electric traction; and if they get the sanction of the Corporation to proceed further, it is highly probable that they will make a beginning with at least 50—possibly 100—accumulator cars, which it is proposed to place on one or more of the east and west tramway lines, all of which are practically level. The General Electric Power and Traction Company have offered to the Glasgow Corporation Committee on Tramways to work the cars for 5d. per car mile, a fact which has given great encouragement to the Committee.

Finsbury Special Lectures.—On January 20th, Mr. A. Reckenzaun begins a course of six lectures on Electric Locomotion, dealing with electric tramways and railways. These will be given on Wednesdays at half-past seven. Through the spring, also on Wednesdays, will be held Mr. Rousseau's practical classes in the new electroplating laboratory, in connection with which Professor Thompson will give three special lectures, on dates to be announced. On February 9th, and succeeding Tuesdays, Mr. W. C. Clinton will give a short course on vector methods of calculation in relation to electrical problems, being an introduction to the writings of Mr. Oliver Heaviside, commencing on February 9th. Professor Perry is continuing his course on the applications of the differential and integral calculus, and will conclude by an exposition of Fourier's theorem in relation to alternate currents and the use of the electrodynamometer in harmonic analysis. Professor Silvanus Thompson continues his ordinary course of Monday lectures, the topics until Easter being transformers, alternate-current motors, and the design of continuous-current dynamos.

The Weston "Flashing" Patent in the States.—There seems to be a plentiful crop of litigation pending before the American Courts. The action of the United States Electric Light Company against the Edison Lamp Company has just been concluded in Philadelphia. The plaintiff Company alleges infringement of the Weston "flashing" patent of 1884 on the part of the defendants. The history of this patent, says the *Electrical Engineer* of New York, is somewhat unusual. In 1878 Sawyer-Man and Hiram S. Maxim filed nearly contemporaneous applications for patents more or less fully describing this process. In December of that year a patent was issued to Sawyer and Man. In May, 1881, Weston made application for a patent for the same invention. After a vigorously contested interference, the Commissioner of Patents decided Weston to be the prior inventor as against Sawyer and Man, and a patent was accordingly granted to him; being the one on which the present suit is based. Considerable difficulty was experienced in procuring evidence of infringement, resort being finally had to the heroic expedient of summoning certain workmen from the Edison Company's lamp factory, and compelling them to testify. A decision is expected shortly.

An Edison Patent.—On December 8th, says the *Electrical Engineer* of New York, a patent was issued to Mr. T. A. Edison, entitled, "System of Distribution," No. 464,822, which will attract considerable attention owing to the broadness of the claims embodied in it. The patent was filed June 26, 1882, and describes the method of employing a high-tension main circuit extending to a distant point and "tension-reducers" located at a distance from the point of supply and connected with the high-tension circuit in multiple arc so as to be independent of one another, the lamps or motors on the derived low-tension circuit also being connected in multiple arc. One method of accomplishing this object is described, consisting of secondary batteries or condensers which are charged in series from the high-tension circuit and discharged in multiple into the low-tension circuit, this being accomplished by means of a revolving commutator. The patent was the subject of prolonged interference proceedings. Claim 1 is as follows:—In a system of electrical distribution, the combination of a main circuit extending to a distance from the source of electrical energy and having a current of high tension, a constantly-acting tension-reducer connected with such main circuit by a multiple-arc or cross-circuit, so as to be independent of other similarly-connected tension-reducers, and a translation-circuit supplied by such tension-reducer with a current of lower tension, substantially as set forth. The Edison Company claims that the patent covers the placing of transformers in multiple arc.

Locating Drum Armature Faults.—In the *Electrical Engineer* of New York of December 16th Mr. O. P. Loomis describes the following method of locating an armature fault:—A monkey-wrench is fastened to the rim of the pulley, or, better still, a crank to the end of the shaft. The fields are excited, and, to make the effects more marked, the coils are connected in parallel. When this has been done the strongest man will scarcely be able to rotate the armature, and then only with extreme slowness, except at one position. When this position has been found mark the armature at points opposite the centre of the pole-pieces and at both ends of the armature. The explanation is that both halves of the armature oppose one another at this position; but when not at these points a continuous circuit is formed, and the resultant magnetic effect is enormous. As the "cross" will be found at one of these four marked points it becomes desirable to know in which one it is most likely to be found. Experience has shown that it is nearly always on the commutator end in the last half of the winding where the wires pass down through the first half terminals. In armatures where the windings are equal Mr. Loomis supposes it would be as liable to be at one point as at another. With this method a defect can be found and remedied in a few moments. These results can be observed in a perfect armature by connecting the opposite sections of the commutator. When only one coil is short-circuited the magnetic effect is much less, and the points must be marked 90deg. from the ones shown; but these cases are few, and are soon discovered in other ways. The above will be understood to apply to armatures of the drum type with Siemens winding.

THE PRINCIPLES OF ALTERNATE CURRENT MEASUREMENT.

BY HUGH ERAT HARRISON, B.SC.

(*Concluded from page 225.*)

Meters and Inductive Circuits.

A meter is intended to record the number of Board of Trade Units supplied to a circuit. The Board of Trade Unit is a unit of energy, but most meters record, not the energy that has passed into the circuit, but the ampere-hours. Indeed, no meter has yet been constructed which will, under all circumstances, measure the energy. It is assumed that the voltage between the mains is kept constant, so that the ampere-hours multiplied by the proper factor will give the number of Board of Trade Units consumed.

The record thus obtained is the same as if the voltmeter and ammeter readings in the circuit were multiplied together, the voltmeter reading being really a constant, since the E.M.F. is supposed to be constant, and the number of watts thus obtained at each instant made to show the energy consumed during the time of observation. It is clearly a matter of prime importance to know whether such a method of measurement will always give a true measure of energy supplied. It has just been shown that if the E.M.F. between the mains of an alternating current circuit would send too large

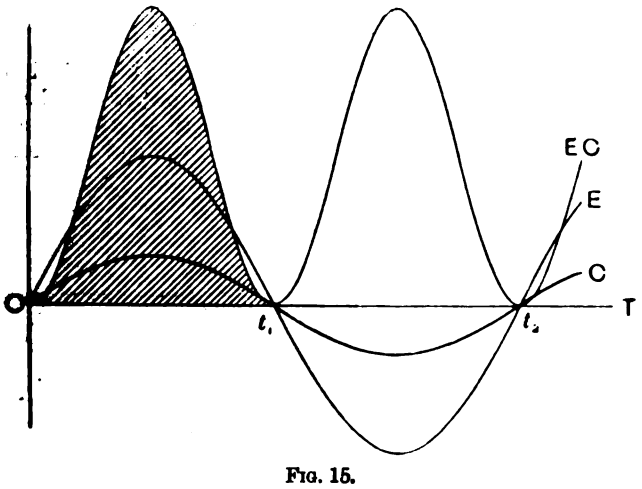

FIG. 15.

a current through any piece of apparatus the difficulty can be got over in one of two ways, the E.M.F. can be reduced to the required amount by the interposition of a resistance coil, or by means of a choking coil. In the first case the complete circuit had a certain resistance and no inductance; in the second case, the resistance was only half that of the first, but there was inductance such that the current was the same in both cases. The currents being the same, and the E.M.F.'s between the mains being the same, two meters, put one on each circuit, will register the same consumption of energy. The true amount of energy used in both circuits will now be considered.

Fig. 15 shows the first case. E is the E.M.F. between the mains, C is the current flowing; the only E.M.F. driving C is that between the mains, so that E and C always have the same direction. If corresponding ordinates of these curves are multiplied together at each instant the curve E C, giving the watts at the same instants is obtained, E C is always a positive quantity because E and C are either both positive or both negative, the E C curve is, therefore, always above the line O T, which means that the circuit is always absorbing power.

The energy used during any interval of time is got by multiplying the number of watts by the time for which they are delivered, hence, the energy during the interval of time O t_1, is equal to the shaded area contained between the E C curve and the line O t_1. If this area be measured it will be found to be exactly equal to the meter reading for a corresponding interval of time. The meter reading is, therefore, perfectly reliable where the circuit has no coefficient of self-induction.

In the second case, the E.M.F. between the mains and the current flowing are the same as in the first, the curves E and C (Fig. 16) are, therefore, reproductions of those in Fig. 15; but their relative position is changed, the C-curve, as shown in Figs. 13 and 14, lagging behind curve E.

The figure is drawn to show the position when the resultant E.M.F. is, as already stated, reduced to half that between the mains by a choking coil.

The power curve E C, whose ordinates are at each instant obtained, as in Fig. 15, by multiplying together the corresponding values of E and C, now dips below O T, for when the ordinates of E and C are on opposite sides of O T, one of them must be negative, and the negative product must be set off below this line. From t_1 to t energy is passing from the mains into the circuit, but from t to t_2 the E.M.F. of self-induction being greater than that between the mains, forces current back into them against their E.M.F., hence energy passes from the circuit into the mains. During a single pulse of the current from t_1 to t_2 the true amount of the energy absorbed in the circuit can be got by subtracting the shaded area below from that above O T, when the quantity will be found to be exactly half that used in the former case.

The meter, say a Shallenberger, is only actuated by the current; it therefore registers the same in both cases, so that the consumer in the latter case will be called upon to pay for exactly double the number of Board of Trade Units that have been supplied to him.

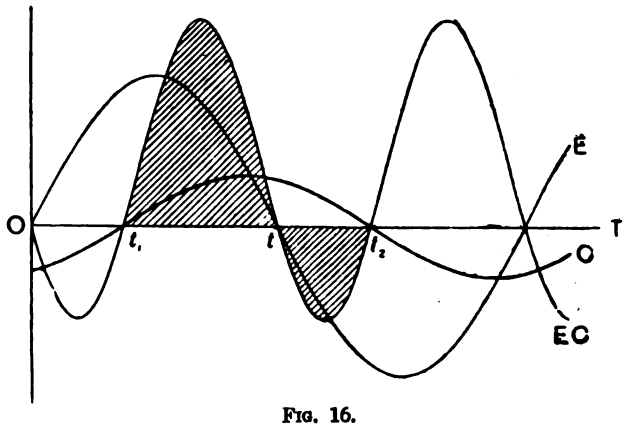

FIG. 16.

The effects due to self-induction are in many ways so unexpected, that those who are only accustomed to work with the unvarying current have some difficulty in seeing exactly how the actions, clearly shown on the curves, really do take place.

That energy *does* actually pass back into the mains and perform useful work, outside the circuit from which it has come, may be seen by taking a simple example.

Suppose that the alternating-current dynamo machine is sending current only through the inductive circuit just considered. From t_1 to t (Fig. 16), the E.M.F. set up in the armature of the dynamo is driving current in the same direction, and the steam engine has to force the armature round. At t the direction of the E.M.F. in the armature reverses, but the current does not reverse until t_2; that is to say, that between t and t_2 current is being forced through the armature against the E.M.F. set up in it. When this occurs, the dynamo is no longer acting as a generator but as a motor. During a complete revolution, for part of the time the dynamo receives electrical energy from the circuit, which it converts into movement for its own use, and the steam engine has only to supply the balance of energy required. On an ordinary circuit, however, the electricity forced back into the mains would not return to the central station, but pass on to supply lamps in a neighbouring house, thus lessening the current the machine has to supply.

From t_1 to t the circuit is, on the whole, absorbing more energy than it can use, so that from t to t_2 it returns what it

Digitized by Google

does not convert into heat; at first it may not be obvious where this energy is stored. The storage of energy received, and subsequently returned, as electrical energy is nothing new. When a current is forced through a secondary battery, but a small fraction of the energy absorbed immediately reappears as heat; the energy is stored up in certain lead compounds, which will give out electrical energy on being allowed to return, by chemical action, to their former state.

When a current passes through a coil having self-induction lines of force spring from it linked with the conductor carrying the current, here it is that the energy is stored, not simply in the coils, but in the space around them pervaded by these lines. When the current falls to zero these lines collapse, and disappear from whence they sprung, but while so doing cut through the path of the current, and return the energy they originally carried with them. The energy stored up at any moment in this form is easily found by multiplying together the ordinates of current and E.M.F. due to self-induction between the point under consideration and that in which the current is zero. The area of the curve so obtained can be shown to be equal to $\frac{1}{2}$ S C^2, S being the coefficient of self-induction.

Conclusion.

It has been assumed that no iron has been used in the circuits through which alternating currents have passed. This has been done in order that varying electromotive force and current might be represented by sine curves, as indeed, is almost always the case in mathematical treatises. In practice a considerable quantity of iron is used with the result that the curves are not true sine curves, and the variation curves are still further departures from them.

The constructions given, however, still hold, the only difference being that the diagrams look more complicated and require more care and skill to draw. Again, the iron causes loss of energy from the circuit, in addition to that due to the resistances of the conductor. Iron, however much laminated, becomes hot when rapidly magnetised and demagnetised. In a choking coil wound with an iron core, therefore, there would be a certain loss even though the coils were of negligible resistance. The aim of this Paper is, however, to be qualitative rather than quantitative, and to explain in their simplest possible forms certain phenomena of the utmost importance, but not very generally understood.

NOTES ON THE PRODUCTION OF A ROTATING MAGNETIC FIELD.

BY H. J. S. HEATHER.

The amount of attention which has recently been devoted to the production of alternating-current motors by the help of a rotating magnetic field, and the very practical advantages that might be secured by the abolition of the commutator, especially in mining machinery, by the adoption of such a system, have led the writer to investigate the claims put forward by Herr Dolivo-Dobrowolsky, in the *Elektrotechnische Zeitschrift*,* of having reduced the pulsations in magnitude of such a field from 40 to 15 per cent. by using three currents, each lagging 60° behind that preceding it, instead of two differing in phase by 90°. This claim, it will be remembered, was based upon the assumption that the currents obtained from an alternator could be represented by sine curves. Recent investigations, however, such as those of Dr. Fröhlich† and Mr. W. B. Lewis,‡ have shown that such a conclusion, although to a certain extent justifiable on theoretical considerations, cannot be regarded as even approximately correct in practice. That the results obtained will necessitate considerable modifications in the figures given by Herr Dobrowolsky is rendered evident in the accompanying Figs. 1 to 8. The curves here given show the nature and extent of the variations which may be expected to actually occur in the strength of rotating fields produced on the two-phase and the three-phase systems. The curves have been obtained from those published by Mr. W. B. Lewis; and in order to facilitate

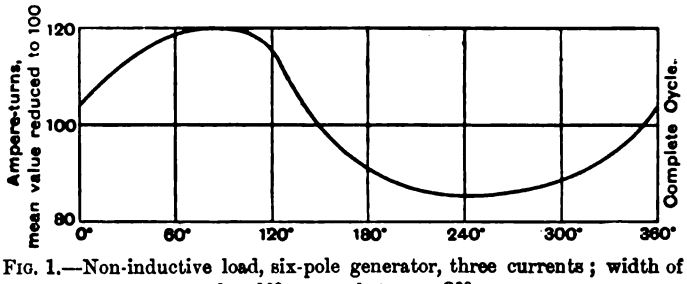

FIG. 1.—Non-inductive load, six-pole generator, three currents; width of poles, 40°; space between, 20°.

comparison reductions have been made, so that in all cases the mean value of the ampere turns is represented by 100. The total variation can consequently be read off as a percentage of

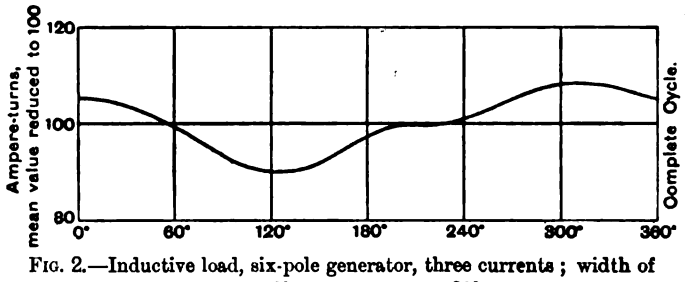

FIG. 2.—Inductive load, six-pole generator, three currents; width of poles, 40°; space between, 20°

the mean value, which seems a more logical method of procedure than that adopted by Herr Dobrowolsky. The latter gives for the variations in the field strength on the two and three-phase systems respectively the figures 40 and 15 per cent.

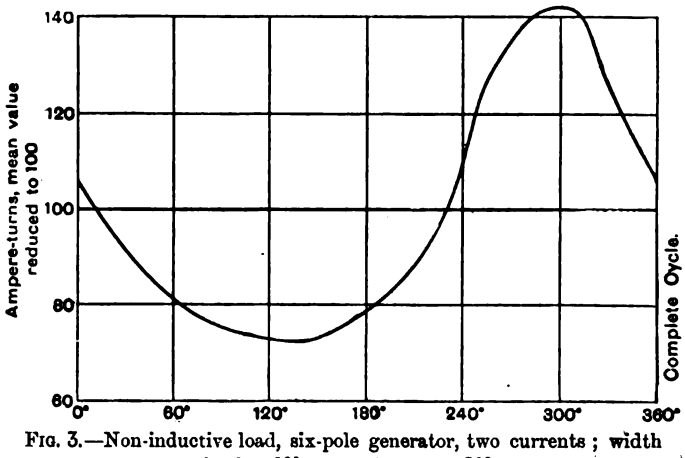

FIG. 3.—Non-inductive load, six-pole generator, two currents; width of poles, 40°; space between, 20°.

These being taken on the maximum values will have to be altered to 32 and 14 per cent. respectively, in order to be compared with the results given herein, in which, as above explained,

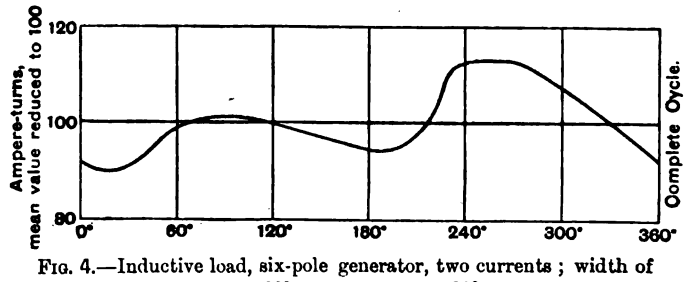

FIG. 4.—Inductive load, six-pole generator, two currents; width of poles, 40°; space between, 20°.

the variations are given as percentages of the mean values. Figs. 1 and 2 are ampere-turn curves obtained by combining three curves similar to those designated as curves 2 and 3 on p. 91 of Vol. XXVIII. of *The Electrician*. The angular width

* *The Electrician*, Vol. XXVII., p. 389.
† *The Electrician*. ‡ *The Electrician*, Vol. XXVIII., p. 91.

Digitized by Google

of the pole-pieces in the machine furnishing this current was 40deg., and the space between them 20deg. In Fig. 1, the load was non-inductive; Fig. 2 being obtained from the inductive load curve given on p. 91. The variation in the former case amounted to 34 per cent. of the mean value, whilst in the latter it is 18 per cent.

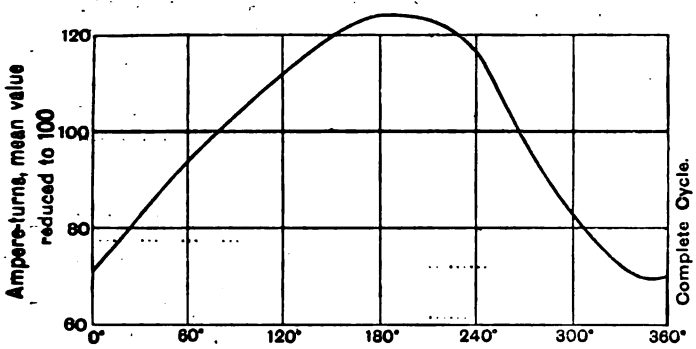

FIG. 5.—Non-inductive load, six-pole generator, three currents; width ..... of poles, 30°; space between, 30°.

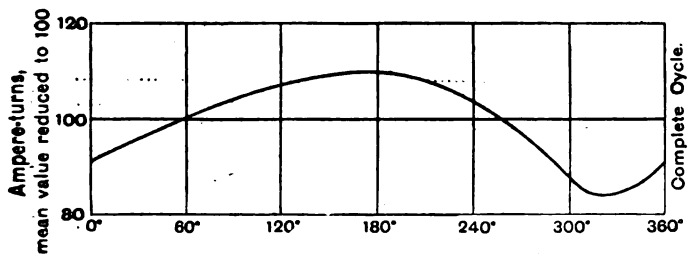

FIG. 6.—Inductive load, six-pole generator, three currents; width of poles, 30°; space between, 30°.

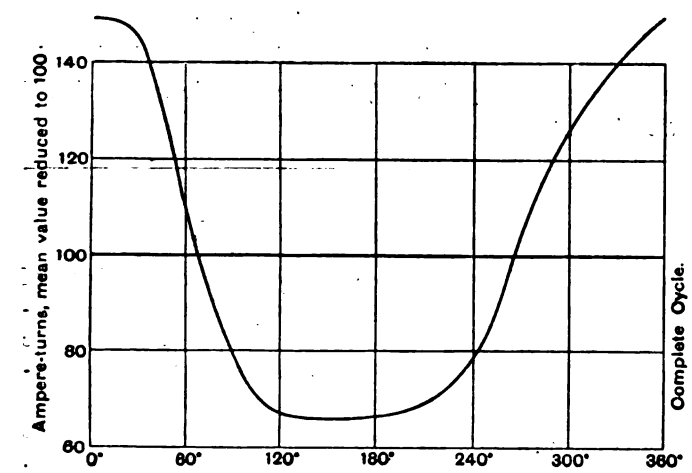

FIG. 7.—Non-inductive load, six-pole generator, two currents; width of poles, 30°; space between, 30°.

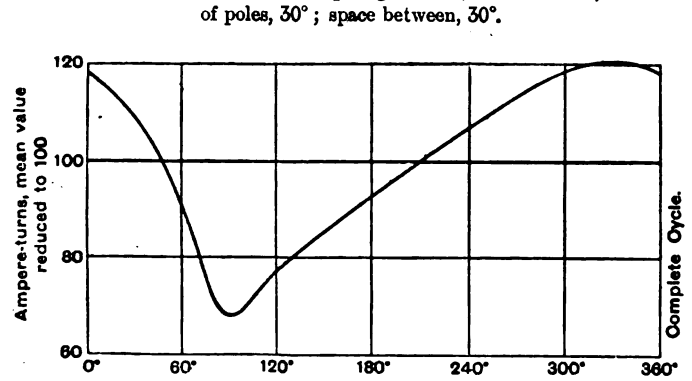

FIG. 8.—Inductive load, six-pole generator, two currents; width of poles, 30°; space between, 30°.

Figs. 3 and 4 give the results of combining two currents from the same machine, differing in phase by 90deg. The variations here become 70 per cent. and 23 per cent. for inductive and non-inductive loads respectively.

Figs. 5 and 6 give the curves for ampere turns on non-inductive and inductive loads, as obtained by combining three currents supplied by a second machine. The variations here are 54 and 28 per cent. Using two currents only, of the same machine, we get Figs. 7 and 8, showing variations of 83 and 52 per cent. The machine used in these four curves had pole pieces, the breadth of which was 30deg., the space between them being also 30deg.

On considering the results obtained it is obvious, firstly, that the design of the machine employed to furnish the multiple-phase currents is of much more importance than the choice between the use of three currents and two; and secondly, that in a machine properly designed for the purpose the advantage gained in steadiness of field strength by the use of three currents instead of two is not nearly so great as Herr Dobrowolsky would have us suppose. Taking, for example, the curves obtained on inductive loads from the machine with the broader poles, we find that the variations are reduced only from 23 per cent. to 18 per cent., instead of from 32 per cent. to 14 as would be the case if the currents could be represented by sine curves. From this it seems clear that the gain in steadiness, amounting only to 5 per cent., secured by the use of three currents with four leads, cannot be considered to correspond with the expense incurred by laying the fourth lead. With regard to the possibility of conveying the three currents by three wires, it may be pointed out that this can only be done at the cost of efficiency, as, owing to the fact that the currents do not in reality follow sine curves, it follows that the sum of two of them is not at all times equal to the third, and consequently at times the volts in two of the sets of coils of the generating machine are attempting to drive a current through the third coil in opposition to that which is induced therein.

ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING.

11 a.m. General Meeting at University College, London. Reports to be presented. Election of Officers.

2 p.m. Papers to be read: (1) "On Laguerre's Dictum concerning Direction." By Prof. R. W. Genese, M.A. (2) "On the Geometrical Interpretation of Fallacy in Elimination." By Prof. R. W. Genese, M.A. (3) "On the use of Horner's Method in Schools." By E. M. Langley, M.A.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "*Coutts and Co.*" *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

SPECIAL NOTICE.—IN ACTIVE PREPARATION.

THE SPREAD OF SCIENCE.

The continual increase in the industrial applications of science has brought about quite a revolution in our educational system, involving a much wider diffusion of scientific knowledge than in former times, at the expense of scholarship, culture, development and training of the mind and character, or, in other words, that preparation for complete living which is the function education has to discharge. Education and culture have been confounded with, and are being swamped by, instruction and teaching. Accepting the situation, however, we are confronted by the fact that after the mere elements have been acquired from text-books, a student who wishes to take up more advanced work, and to make himself familiar with recent developments and applications, must turn to Papers read before, or presented to, learned societies. Now the extent to which the publication of Papers on scientific subjects has developed owing to the multiplication of colleges and universities and of scientific societies is enormous. Twenty years ago it was comparatively easy for a scientist to keep himself in touch with all the experimental work carried out in connection with his own special department; but this is now quite out of the question, in consequence of the great number of workers and the endless publications that would have to be perused in order to accomplish his object. Science is no longer a purely intellectual calling, followed from the love of knowledge or the desire for fame. Its commercial applications have become so numerous and important that many follow it for mere gain. The advantages

Digitized by Google

thus accruing to science are of considerable value, and although commercial men still sneer occasionally at abstract scientific investigation, the great debt which industry indirectly owes to pioneer work has been more than repaid by rich endowments of general research, and by a number of large scale industrial developments which have had a marked influence on the progress of pure theory. The theoretical importance of the induction researches of FARADAY could not have been recognised to anything like their full extent had it not been for the development of the dynamo machine; while the investigations of HERTZ and MAXWELL'S great theory which explains them, would have been unintelligible, save to a few mathematicians, were it not for the familiarity with alternate-current phenomena brought about by commerce, and by commerce alone.

These developments are, however, not all healthy, for, in some respects, scientific progress is being choked by its own rapid growth; and while scientific papers increase in number they do not increase in value. Nowadays each town wants an educational establishment which calls itself a university, and each of these has its physical society. Formerly scientific publications were few and expensive, and it was always worth while to attend the meetings of a scientific society. But it is now possible to procure, at a trifling cost, weekly or monthly publications which reproduce, in full or in abstract, the more important of the current Papers published in all parts of the world. These can be read in leisure moments, and the articles which do not interest can be passed over; whereas attendance at a meeting involves a great expenditure of time, and often results only in the hearing of a dull or poor Paper. This fact may serve to explain the absence of many of the best, and hence the busiest, men from scientific discussions; and, indeed, there are so many societies now that a feeling of satiety is excusable. The technical journals are to a great extent usurping the functions of the scientific bodies by publishing original matter straight away; and many prefer this method of giving their results to the world because it secures wider and prompter publicity, and because there is not so much danger of a valuable Paper being lost when it is printed in the columns of a widely circulated journal. This danger of burying a good Paper amid the bewildering mass of contemporary science is by no means imaginary, and is becoming greater and greater every year. People have very little time to read Papers, and they have much less time to criticise them. The hasty way in which people read has naturally a bad effect on those who write, and but few Papers now are well and clearly written. Many rush into print with experimental matter the results of which are too incomplete to be really worthy of publication; while others who are well qualified to speak with authority are far too busy to find time to put into proper publishing form the great mass of interesting and important results constantly occurring in the course of their work. There is too great a tendency on the part of writers to expand mere details in order to make a lengthy communication.

Things have already come to a such a pass that it is almost impossible for anyone to read more than a fraction of the literature referring to his own special class of work, and science is spreading so rapidly that in the near future matters may be expected to be much worse. It is not easy to suggest a remedy. What perhaps is needed is a clearly written and complete series of classified abstracts, giving the gist of what has been published. The question of ways and means, important as it is, is, however, hardly the most difficult one to solve. The greatest difficulty would be to find properly qualified men to do the work. The qualities of a good literary reviewer are not at all those which are needed for the scientific abstracter. In the former we look for well-balanced comments and personal opinions, while in the latter we want clearness and brevity in the exposition of difficult matter and the total abandonment of everything personal. Nothing is more difficult than really good abstracting, and the author himself is often quite incapable of generalising his results and expunging details. The abstracter must be interested in his subject; that is to say, he must be experimentally familiar with it; and the matter must be somewhat fresh to him, or he will grow tired, fail to grasp the Paper as a whole, and make an unsatisfactory summary. The scientific societies could do much to forward this work either singly or in combination. We have already pointed out that the technical Press has relieved these bodies of the need of publishing results, and the aim of societies should now rather be the discussion of Papers which have *not* been read before them, than, as too often happens, the reading of Papers at such length that no time is left for discussion. The *raison d'être* of all societies and similar institutions is the bringing together of birds of a feather for the critical examination of new devices, discoveries, and theories, and the collection and editing of scattered scientific memoirs. It is true that some of the societies attempt work of the latter kind. The Physical Society have translated and published some very valuable foreign memoirs. The Chemical Society issue with each section of their Journal an important series of abstracts. The Institution of Civil Engineers has a regular staff of translators and abstracters, who collect descriptions of new works, inventions, and processes from foreign journals, as well as Papers presented to learned societies. The Institution of Electrical Engineers does a little less of this kind of work every year. Methodical abstracting is, however, becoming more and more necessary to prevent valuable matter from being utterly lost, and this work is clearly the business of the scientific societies.

OBITUARY.

SIR GEORGE BIDDELL AIRY.

The death of Sir George Airy removes from the general scientific world a most rigid mathematician; while the mathematical world loses one who has for the last seventy years devoted his rare abilities to the application of mathematics to astronomical and allied problems. Sir George Airy was born in 1801, entered Trinity College, Cambridge, in 1819, and graduated as Senior Wrangler in 1823. In the next and following years he published Papers on Lunar and Planetary Theories, the Figure of the Earth, Undulatory Theory of Optics, the Forms of the Teeth of Wheels, and on Escapements. In 1826 he was elected Lucasian Professor of Mathematics, and, two years later, Plumian Professor of Astronomy. From this time he applied himself with the greatest activity to both the development of important planetary and other astronomical theories, and to the arrangement of the routine of observations, upon which all good observatory work depends. In 1836 he was appointed Astronomer-Royal. It is not necessary to allude here to the invaluable services which he rendered to exact astronomy during his long tenure of office; but we must not allow the establishment of magnetic observations at Greenwich to pass without mention. Amongst other useful work outside the observatory, Sir George Airy turned his attention to the deviation of the compass in iron ships, and was Chairman of the Commission appointed to consider the general question of Standards, and of the Commission intrusted with the superintendence of the new standards of length and weight after the fire which destroyed the Houses of Parliament in 1834.

The best known work of Sir George Airy is his "Treatise on Errors of Observation," published in 1861. Nine years afterwards he published a "Treatise on Magnetism"; and in the

Digitized by Google

following year (1871) he was elected President of the Royal Society. He was a man of immense industry and highly-trained intellect, and a severe disciplinarian. His mathematical powers were of that kind which are best applied to specialist's work; and his official position as Astronomer-Royal, in directing his attention mainly to that science which first occupied his attention as a young man, concentrated his energies on work for which he was eminently fitted, and resulted in the development and equipment of the Greenwich Observatory, the organisation of eclipse and transit expeditions, and the still more permanent record of his labours in the bulky volumes which contain the reduction of observations and other direct contributions to astronomical science.

FREDERICK RICHARDS LEYLAND

Mr. F. R. Leyland, the Chairman of the National Telephone Company and Deputy-Chairman of the Edison and Swan and also of the Swan Company, died very suddenly on Monday afternoon last. Mr. Leyland, after spending some hours at the Telephone Company's office, left with Colonel Raynsford Jackson, both gentlemen going to Cannon-street Station of the underground railway. After leaving that station he became very ill, and at Blackfriars he had to be taken out of the train, and a doctor was sent for, who, on arrival, found him dead. Mr. Leyland was 61 years of age. The death of Mr. Leyland will prove a serious loss to the Companies with which he was connected. Since his appointment to the Presidentship of the National Company he had thrown himself heartily into the work, and devoted almost all his time to the business of the Company, although he was a man of wealth, and had retired from active business before his connection with the telephone company began.

Mr. Frederick R. Leyland, who was head of the great shipping firm of Liverpool known as the Leyland Line, has passed the greater part of each year for several years past in London, leaving the executive responsibility of the business in Liverpool to his son, Mr. Frederick D. Leyland, and his manager, Mr. Martin, though he has always spent the autumn in Liverpool. Mr. Leyland's career was most remarkable. At an early age he was placed in the office of the well-known shipping firm of Messrs. Bibby and Co. By his talent and industry he rose to be manager of the firm, and while still a young man was taken into partnership. When some years ago the partnership came to an end by effluxion of time Mr. Leyland carried on the business alone, since which time he has extended the business very much, and has been for some time probably the largest and most wealthy individual owner of ships in the world.

Shortly after the Edison Company was formed, in 1882, Mr. Leyland was invited to join the Board. He, however, had only attended two or three Board meetings when the amalgamation with the Swan Company was resolved upon, and he became one of the first Directors of the Edison and Swan Company; and at the end of the first year of the amalgamated Company he was appointed Deputy-Chairman. His colleagues, one and all, have always recognised that no small share of the success which has attended the "Edison and Swan" has been due to the courage, the ability, the industry, resource, and resolution of Mr. Leyland, than whom no better man of business has ever migrated from Liverpool to London. In December, 1884, he became a Director of the Swan Company, and he has devoted a great deal of time and has spared no effort to make both of these electrical companies worthy of the great industry with which they are concerned.

About three years ago Mr. Leyland was invited to join the Board of the United Telephone Company, and took an active and leading part in the delicate and difficult negotiations preceding the amalgamation which resulted in the formation of the important Company which works throughout England under the name of the National Telephone Company, of which at the first meeting of the Board he was chosen President. Since his appointment as President he has thrown his whole energy into the work; he has attended in Oxford-court three or four days a week, and for many hours a day, and the great increase in the business, and the encouraging prospects of the Company, are in no small degree due to Mr. Leyland's devotion to the interests of the concern.

Mr. Leyland was a man of great wealth, his house in Princes-gate, known throughout the world for its beautiful "peacock room," decorated by Mr. Whistler, contains the best collection in London of pictures by Boticelli, Rossetti, and Burne Jones. Mr. Leyland leaves one son and two daughters, Mrs. Val Prinsep and Mrs. Speed. Mr. Leyland was a self-educated man; he knew and could speak French, Italian, and Spanish, besides being a great lover of art and a consummate judge of pictures; he played the piano admirably, and often, after a hard day's business, he sought relaxation by playing the masterpieces of Beethoven, Mozart, Liszt, and Chopin by the hour together. There are not many more remarkable instances to be found in the annals of commercial life than the rise of Frederick Richards Leyland from the humble position of a boy in the office to the head of the great firm of "Leylands," of Liverpool, teaching himself, as he did, arithmetic, French, Italian and history—even when 14 years of age working on night after night at these subjects till 2 a.m. in order to try to make up for the stern necessity which, owing to his father's death, sent the poor little uneducated Lancashire lad, at 13 years of age, to earn his own laborious and precarious living.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 192.*)

§ **47. Elementary Theory of Circular Circuits.**—We shall now consider a few cases in which the coefficient of mutual induction, M, for a pair of circuits can be easily calculated, and shall also determine the force acting between them. Let there be two circular circuits, with their planes parallel, and the line joining their centres perpendicular to these two planes. Let A, Fig. 42, be the radius of the larger, a that of

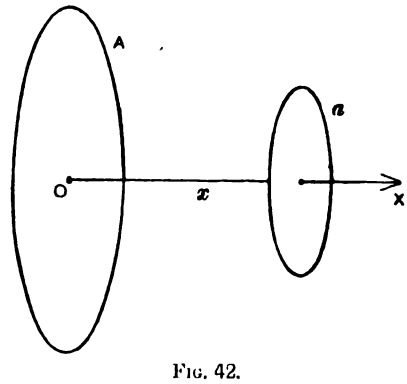

Fig. 42.

the smaller circle, and x the distance between the centre of the circles. To find M we have to find the number of lines of induction which pass through a (carrying no current) when unit current flows in A. In this case we shall make use of the "First Method" of § 43. If a is small compared with A, we may consider that the magnetic induction is uniform all over the plane area bounded by the circle a. By § 26 or § 33, the magnetic force at a point on the axis at a distance x from the centre of the circle A, due to unit current in A, is $F = 2\pi A^2/(A^2+x^2)^{\frac{3}{2}}$, and its direction is along the axis. Since we are dealing with air, this is also the magnetic induction. Hence the number of lines of induction which pass through a, whose area is πa^2, is $M = 2\pi^2 a^2 A^2/(A^2+x^2)^{\frac{3}{2}}$ per unit of current in the coil A. If currents, i, i', flow in the same direction round the circuits A, a, then, by § 44, the force acting on a tending to increase x, is $X = i\,i'\,dM/dx$ dynes. Hence, in our case, $X = -6\pi^2 a^2 A^2 x\,i\,i'/(A^2+x^2)^{\frac{5}{2}}$ dynes, the negative sign implying attraction. When x is small compared with A the force is nearly proportional to x, but when x is large compared with A, then the attraction is nearly proportional to $1/x^4$, so that it

Digitized by Google

very soon becomes exceedingly small. To find when the attraction is a maximum we must put $dX/dx = 0$. Performing the differentiation we easily find that this condition is satisfied when $x = A/2$. When the coils are placed at this distance apart the force between them has its greatest value, and consequently is not altered by any very small change in x. To give some idea of the magnitudes of the quantities we are dealing with, we have calculated M and dM/dx for various values of x taking A = 50cm. $a = 10$cm. We notice that since M is of the *dimensions* of a line dM/dx is a pure number and is quite independent of the standards of length, mass, or time. When multiplied by the product of the two currents it gives the force in dynes.

x centimetres.	M centimetres.	dM/dx.
0	39·47	0
10	37·21	·4294
25	28·2491	·677963
50	13·95	·4187

If there are n turns on the coil A and n' on the coil a, and the windings occupy a space which is very small compared with the radius of either coil, both M and $d\,M/d\,x$ will be $n\,n'$ times as great as before. Thus, if there were 1,000 turns of wire on the large coil and 100 on the small one, we should have when $x = 25$ cm. $M = 28{\cdot}2491 \times 10^5$ centimetres $= {\cdot}0028491$ henry, $d\,M/d\,x = {\cdot}677963 \times 10^5$.

Now, suppose that the same current of 1 ampere is flowing in both coils. The value of the ampere in C.-G.-S. units is 1/10. (*See* § 23.) Hence the *attraction* between the coils under these circumstances is $-X = -i\,i\,d\,M/d\,x = {\cdot}677963 \times 10^3 = 677{\cdot}963$ dynes. But the *weight* of 1 gramme at Greenwich is 981·17 dynes, so that X is equal to the weight of ·6909 grammes at Greenwich.

§ 48. **Elementary Current Weigher.**—If we can actually measure this force we can at once deduce the value of the current flowing in the two coils without any reference to such

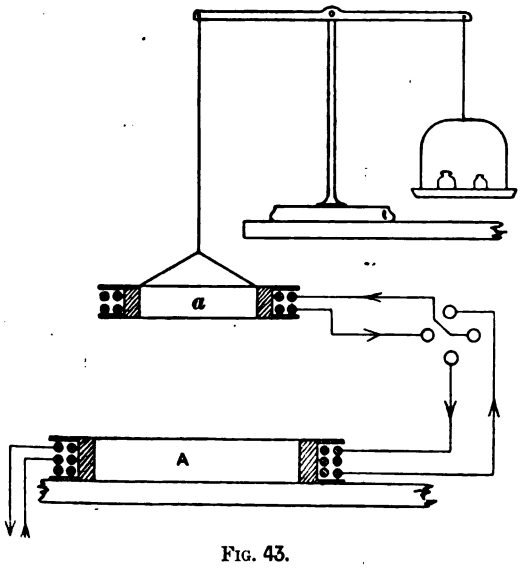

Fig. 43.

uncertain quantities as the strength of the Earth's Horizontal Magnetic Field, as in the case of the Tangent Galvanometer. The force of attraction can be measured by suspending the small coil from an arm of a balance (Fig. 43). The same current is sent round both the coils A and a, being led to and from the latter by a number of very flexible copper wires arranged "in parallel." A commutator is arranged so that the current in the suspended coil can be reversed without reversing that in the fixed coil. When the currents flow in the *same* direction, the electro-magnetic force is an *attraction*, when they flow in *opposite* directions a *repulsion*. The weight of the difference of the masses required to balance the suspended coil in the two cases is twice the electro-magnetic force experienced by that coil in either case. If $2m$ is the difference of the masses in grammes, and g the value of "gravity," we have

$$m\,g = \frac{6\,\pi^2\,n\,n'\,A^2\,a^2\,x}{(A^2+x^2)^{\frac{5}{2}}} \cdot i^2,$$

where n, n are the numbers of turns on the two coils. From this equation we can at once determine the value of i.

Since the force depends upon i^2 it is independent of the direction of the current, so that this method is available for the measurement of an alternating current. In this case the value of i deduced from the equation gives the square root of the time-average of the square of the current. This is called the "effective current," as an English equivalent of the definition agreed to at the Electrical Congress at Paris in 1889. (*See* report on "Electrical Standards," British Association Report, Newcastle, 1889.)

§ 49. **Best Positions for the Coils.**—We gain considerably in accuracy by placing a second fixed coil on the other side of the suspended coil, the second coil being exactly similar to the first. Let the planes of the two fixed coils be at a distance $2\,b$ apart, and let the suspended coil be at a distance $b+z$ from one fixed coil, and consequently at a distance $b-z$ from the other; z is supposed to be small. We then find by Taylor's theorem that the values of $\frac{d\,M}{d\,x}$ for the suspended coil and each of the two fixed coils are

$$x = b+z,\quad \frac{d\,M}{d\,x} = \left(\frac{d\,M}{d\,x}\right)_b + z\left(\frac{d^2\,M}{d\,x^2}\right)_b + \frac{z^2}{1\cdot2}\left(\frac{d^3\,M}{d\,x^3}\right)_b + \ldots$$

$$x = b-z,\quad \frac{d\,M}{d\,x} = \left(\frac{d\,M}{d\,x}\right)_b - z\left(\frac{d^2\,M}{d\,x^2}\right)_b + \frac{z^2}{1\cdot2}\left(\frac{d^3\,M}{d\,x^3}\right)_b - \ldots$$

where the suffix b attached to any quantity means that x is to be put equal to b in that quantity *after differentiation*. The sum of these two expressions is

$$2\left\{\left(\frac{d\,M}{d\,x}\right)_b + \frac{z^2}{1\cdot2}\left(\frac{d^3\,M}{d\,x^3}\right)_b\right\} + \ldots$$

so that the error introduced by a small displacement of the suspended coil from the central position depends upon the square of that displacement. Hence, with moderate care in the adjustments, the force experienced by the coil may be considered to be the same as in the exact central position.

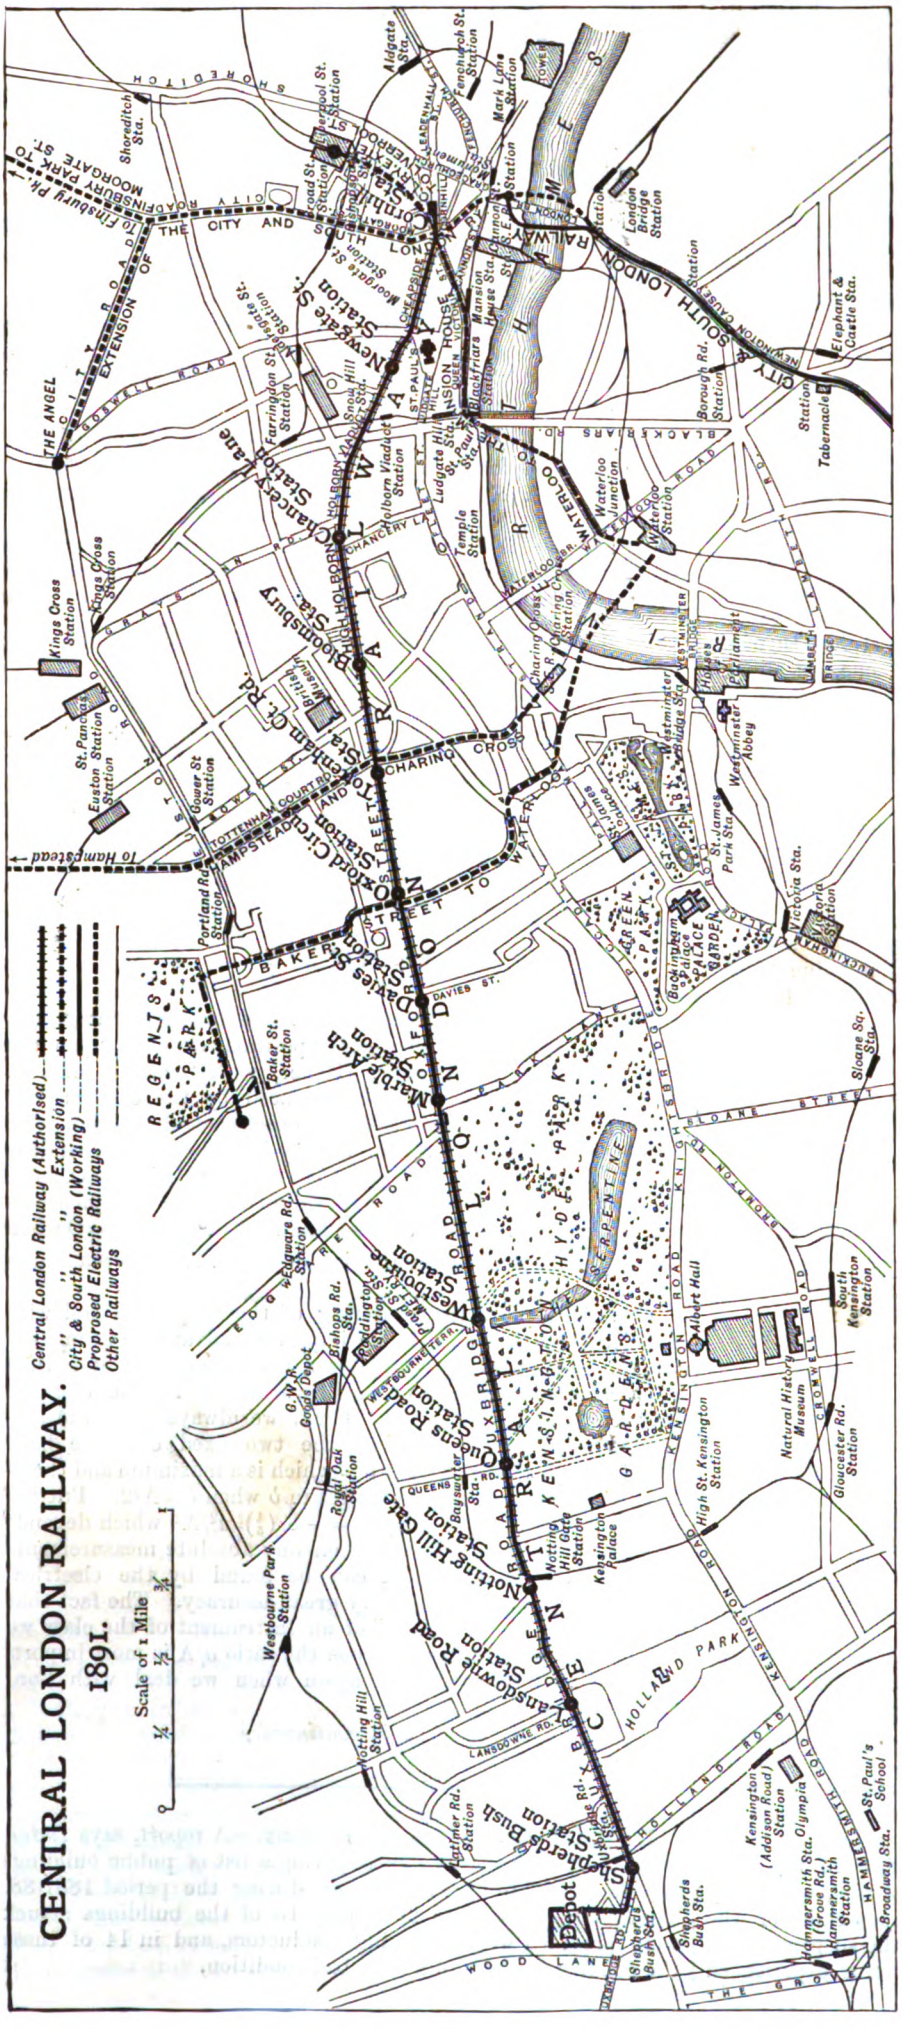
We may make the force in a very high degree independent of small displacements if we chose b so that $(d^3\,M/d\,x^3)_b = 0$, since the first term which then appears involves z^4 and hence is extremely small. In our case we find that $(d^3\,M/d\,x^3)_b = 0$ when $b = A.\sqrt{3}/2$, but the attraction is now only ·747 of its maximum value.

If we can effect the centering of the suspended coil with sufficient accuracy we gain an important advantage in making $b = A/2$, so that the attraction is a maximum, since it is then practically independent of small variations in the distance between the two fixed coils. For if we always place the suspended coil midway between the two fixed coils we have $d\,M/d\,x = -6\,\pi^2\,a^2A^2\,b/(A^2+b^2)^{\frac{5}{2}}$ which is a maximum and therefore independent of small changes in b when $b = A/2$. Putting in this value we find $d\,M/d\,x = -6\,(\frac{4}{5})^{\frac{5}{2}}\,a^2/A^2$ which depends only on the ratio a/A and not on any absolute measurements of lengths. The ratio a/A can be found by the electrical method given in § 29 with very great accuracy. The fact that the fundamental "constant" of an instrument of the class we are describing depends only upon the ratio a/A is most important; we shall return to it again when we deal with Lord Rayleigh's work.

(To be continued.)

Lightning Conductors in Germany.—A report, says *Industries*, has been recently issued, giving a list of public buildings struck by lightning in Germany, during the period 1887-88. The total number was 264; only 15 of the buildings struck were provided with lightning conductors, and in 14 of those the conductors were in a very bad condition.

Digitized by Google



ELECTRIC RAILWAY ENTERPRISE IN LONDON.

The first point to be noted on the map which we publish this week is the route of the existing Underground Railway, the "circle" of which is somewhat of an oblong, being about five miles long by two miles broad, circumscribing the very heart of the metropolis. The weak feature of the Underground Railway is, however, that it is circular; it rarely happens to be the shortest route to a given place. Another defect is that, although closely adjacent at different points to all the termini of the large trunk lines, it does not actually run through any of them, with the exception of Cannon-street. Paddington, Victoria, and Liverpool-street, are, indeed, accessible by means of subways; but with the far more important Stations of Euston, St. Pancras, and King's Cross there is no "physical junction." The electric railways now in operation, authorised, and projected, propose to meet these and the many other still more serious defects of the existing Underground Railway.

The Central London Railway, with its proposed extension from the Mansion House to Liverpool-street Station, will cut straight across the heart of London from East to West, connecting the residential districts of Bayswater and Notting Hill with the shops of the West and the business quarters of the City. It is not unreasonable to expect that this line will have a fairly heavy *all day* traffic; since after the rush of the business men going inwards in the morning, there will be a constant stream of "shoppers" out and home before the return rush from the City takes place in the evening. The line from Waterloo across the West End to Baker-street supplies a long-felt want, for between the large residential districts north of Baker-street and the leading thoroughfares of the West End, there is at present no adequate mode of conveyance. The line which it is proposed to run from Charing-cross to Hampstead Heath will make this "open space" easy of access, and will also place an important residential district in closer communication with the shopping and business quarters of London. Perhaps the line most needed is the short one from Waterloo Station into the City. Hundreds of suburban and main line trains run in and out of Waterloo every day; and yet the only means of getting across the river into the City has been by a circuitous railway journey, the omnibus, or cab. The extension of the City and South London Railway northwards into the populous district of Islington will probably prove a very profitable one to that Company, since, so far as direct railway communication is concerned, the North and South of London are at present almost entirely cut off from each other. The line from Finsbury Park to Finsbury-pavement will, it is to be hoped, diminish the sometimes dangerous and always disgraceful overcrowding of the Great Northern trains running in and out of Moorgate-street.

Digitized by Google

The fate of the four new lines and two extensions which will come before the Legislature this Session depends, of course, on the exigencies of the political situation. If Parliament is dissolved suddenly and early, we may say good-bye for the next twelve months to all of these enterprises.

THE CRYSTAL PALACE EXHIBITION.

We have visited the Crystal Palace with the object of being able to give our readers some idea of what may be ready for inspection on Saturday, when the Exhibition is to be formally opened. Two or three days, however, will no doubt largely increase the number of completed stalls, which were but few and far between at the time of our visit. Among those which may be expected to be quite ready is the Post Office exhibit, which will be one of even greater interest than usual. The instruments will be arranged in chronological order on four tables, each about 100ft. long—the tables being arranged in pairs. On one pair will be instruments used during the period 1851—1870, and on the other pair those subsequently in use down to the most modern.

The Brush Company's space was well filled with trim and compact little combined plants, consisting of "Brush" engines coupled direct to "Victoria" dynamos. Some of the latter have the field-magnet coils enclosed in metal cases, and look an exceedingly good job, the finish and workmanship alike being first class. Mordey alternators were in course of erection; and a number of transformers in cast-iron cases, each having a switch—presumably, on the primary—the lever of which projects through the casing and ends in a porcelain handle, were lying about the stand. One of the hollow wrought-iron poles for arc lamps, having all the gear arranged inside—of the pattern first used at the Manchester Exhibition—stands in the centre of the stall, and carries six arcs.

Messrs. Crompton had a fair assortment of their well-known types of dynamos on the ground, and the electric crane was in position.

Woodhouse and Rawson United have a Kingdon alternator, and an electro-hydraulic rivetter was also in position. This consists of a multipolar motor, which is enclosed by an almost globular cast-iron shell, from the inside of which the magnets project towards the centre. The commutator is accessible from an opening at one end, and the current is conveyed by two brushes only, which are at an angle of 60deg. apart, there being six poles to the magnets. The motor operates a wheel which has a square screw-thread cut through its boss, in which fits one end of a plunger. This is kept from rotating, and passes through a gland into a water-filled space, from which issues the plunger, which ends in the rivetting punch.

Messrs. J. White and Co., of Glasgow, have a good assortment of Sir William Thomson's new standard balances. They also have an instrument (also Sir William's) for measuring up to 50,000 volts. Another interesting appliance on their stand is a voltapile; this has been in use at Messrs. White's factory for some time for calibrating multicellular voltmeters. It consists of 400 zinc-copper couples, of flat section, of inverted ∩ shape, supported by an insulating plate. The couples are mounted so as to leave only a small space between the zinc of one couple and the copper of another, the space between the two legs of a single couple being several times greater. Terminals are provided at the extremities of the series. When the pile is required for use the projecting zinc-copper legs are dipped into a bath of water, and when withdrawn a drop of water is retained between the opposed plates of adjacent pairs, so that a difference of potential of about 400 volts is produced. The pile is, of course, quickly polarised if any current is allowed to flow. A standard instrument is, of course, used in calibrating. Messrs. White also show an instrument arranged so that by a simple adjustment it can be made to read directly the number of lamps in use on a circuit, supposing them all to be similar and of the same candle-power. The wire-work was in position for the Edison-Swan Company's "screen of lamps."

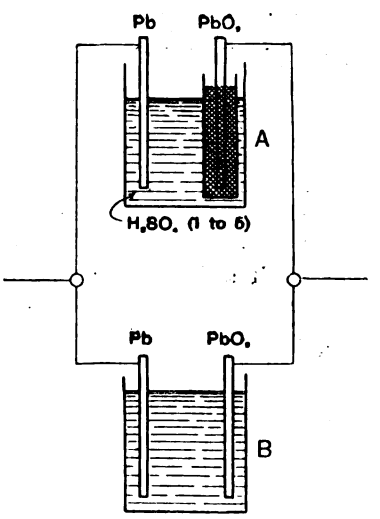
The Fowler-Waring Company, who are laying the mains from the Sydenham station to the Palace, have had considerable difficulty in drawing in their cables, owing to the manner in which the pipes have been laid, and it is to be sincerely hoped that no damage has resulted to the insulation. The pipes are of porcelain, of about 5in. bore, each pipe contains three cables, apparently of 19/15's. The insulating coating is about ·15in. thick, and the lead ·1in., the pressure being 1,000 volts continuous. We witnessed the joint-making; and both the insulating and plumbing were being carried out in a very thorough and workmanlike manner, as, indeed, might have been expected.

One interesting feature of the Exhibition will be the concert room of the National Telephone Company, where, on payment of a small admission fee, the public will have an opportunity of listening to the music performed at theatres in London, Birmingham, Manchester, and Liverpool.

SOME SECONDARY-BATTERY EXPERIMENTS.

A few days after the reading of his Society of Arts Paper (see *The Electrician*, December 4th, 11th, and 18th), Mr. Robertson was good enough to repeat for us the experiments with which he concluded his Paper; and, as they were not of a nature to be clearly seen by the majority of his audience, the following brief note may be of interest.

Cells A and B, which were of a diminutive description, were both charged from a battery of Daniell cells for about forty minutes. In A the peroxide and the lead plates were separated by a porous pot; in B there was no separation.



On taking the electromotive forces with a low-resistance twisted-strip voltmeter, that of A was found to be low (about 1·3 volt), while that of B was a trifle higher, but neither would give a deflection for long. On interchanging the plates of A, the voltage fell but slightly, and this was followed by permanent running down. The acid of A was then tested by the addition of potassium iodide, using starch as an indicator, and "active oxygen" was found to be present at *both* plates, accounting for the low electromotive force and the small effect of interchanging the plates. Acid was next taken from B, and poured on to some pure lead peroxide; there was no immediate evolution of oxygen, but after a time it was slowly liberated, proving the formation of *hydrogen dioxide* (H_2O_2) in the electrolysed acid, since persulphuric acid ($H_2S_2O_8$) does not affect peroxide of lead. A little hydrogen dioxide was then added to the acid of B, and caused a slight initial rise of E.M.F. followed by a permanent fall. Testing the acid used for making up the cells it was found to give no blue with potassium iodide and starch, showing plainly that it is the electrolysis of the acid which gives rise to the hydrogen dioxide.

Digitized by Google

The plates of A were now taken out, and placed in an otherwise entirely fresh cell and charged for a short time. The electromotive force was about 1·7 volt, and interchanging the plates reduced it to zero. The plates were then restored to their original relative positions, a fresh lead plate being used. The electromotive force immediately rose, showing that the previous fall had been caused solely by the action of the acid on the *lead* plate. Transposing the plates again reduced the electromotive force to zero.

This cell, C, was now tested to discover the distribution of the "active oxygen"; and the acid next the lead plate when the plate was placed so that the electromotive force of the cell was high, was practically free from it.

These simple little experiments, which anyone who possesses a few Daniell and miniature storage cells, and some chemicals and test tubes can repeat for himself, may be taken as tolerably conclusive bases for Mr. Robertson's three main theses. (i.) With H_2O_2 generally distributed in a cell we shall have low electromotive force. (ii.) With H_2O_2 concentrated around the peroxide plate, we shall have high electromotive force. (iii.) With H_2O_2 concentrated around the lead plate, we shall have next to no electromotive force. Persulphuric acid is the primary product of the electrolysis of sulphuric acid, and, being unstable, begins to break up the moment the charging current is stopped, and combining with the electrolyte forms hydrogen dioxide, which gets gradually diffused through the cell, oxidising the lead plate to litharge and reducing the peroxide plate to the same substance, the litharge so formed being finally converted into sulphate by the sulphuric acid. A cell containing electrolysed acid, and left at rest for a long period at a time, is evidently, therefore, on the road to ruin unless treated with some such catalytic agent as Mr. Barbey Starkey's sodium carbonate.

THE PARSONS STEAM TURBINE DYNAMO,

The following report, by Prof. J. A. Ewing, of some trials of a 100-unit Parsons steam turbine dynamo at Heaton Works, Newcastle-on-Tyne, was submitted at an inquiry held by the Local Government Board on December 30, 1891, with regard to proposals of the Corporation of Cambridge to adopt a scheme of electric lighting:—

The machine tested is, I am informed, the first condensing steam turbine that Mr. Parsons has built. Its shaft was designed to carry six small and one large plate or disc, each fitted with a series of rings of turbine blades, the large plate being specially designed to deal with low-pressure steam. After passing it, the steam was exhausted into a jet condenser of novel design, the pump of which was driven by a separate donkey engine. The turbine rings were of the outward flow type.

The turbine was designed to work with steam at an initial pressure of 140lb. per square inch, but on the occasion of the trials it was not practicable, for want of a suitable boiler, to use a pressure of more than 95lb. per square inch. The first and second plates, with their turbine blades, were accordingly removed, and the tests were made with the remaining four small and one large plate. The effect of this was to make the results of the trials less favourable, as to economy in steam consumption, than they would have been had the full initial pressure of 140lb. been available.

In line with the turbine shaft, and directly coupled to it, was the armature of an alternate-current dynamo capable of yielding 100 kilowatts, or 100 Board of Trade units of electrical energy per hour, and wound for a potential of 2,000 volts. The exciter was a distinct small dynamo of the continuous-current Gramme type, which was also mounted on a prolongation of the turbine shaft.

The turbine ran at a speed of about 4,800 revolutions per minute, and the armature was wound with a single coil, so that the frequency of the alternations was about 80 complete periods per second.

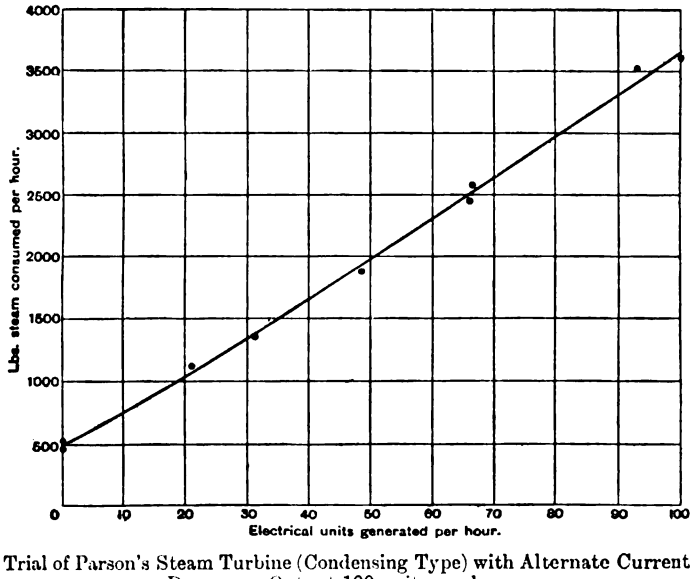
The whole machine, comprising the turbine, dynamo, and exciter, weighed about four tons; its length was about 14ft., and its greatest breadth barely 3ft. It stood on three cast-iron pedestals resting on an ordinary concrete floor. There were no holding-down bolts or special foundations, and none seemed to be required. The machine ran almost without vibration.

In the trials the current generated was spent on a bank of resistance coils consisting of open spirals of iron wire strung on wooden frames. The output was varied, in successive trials, from about 20 units per hour, or, say, one-fifth load, to 100 units per hour or full load. The loads spoken of are the amounts of electrical power spent in the external circuit, and do not include the work done by the exciter in supplying current to the field-magnets of the main dynamo. (The output of the exciter was about 2½ units per hour.)

In two additional trials there was no external load beyond what was necessary for measuring the potential.

The experiments were arranged to give complete information of the amount of steam used by the turbine under all grades of output, from full load to zero.

The electrical output was taken to be the product of the effective volts at the dynamo terminals into the effective amperes. The volts were measured by aid of a 2-H.P. transformer, which transformed down in the ratio of 1 to 10, and a pair of Cardew voltmeters. To test the accuracy of the professed ratio of transformation, the volts were on one occasion read by applying a Cardew voltmeter to successive portions of the bank of resistance coils (then grouped in series) so that the potential was directly determined by summing up the readings. This determination was found to agree exactly with that obtained by means of the transformer.



Trial of Parson's Steam Turbine (Condensing Type) with Alternate Current Dynamo. Output 100 units per hour.

The Cardew voltmeters were themselves tested by comparison with a third Cardew, which in its turn had been standardised by help of one of Sir William Thomson's balances. They were found to be correct.

The current was measured by (1) an Evershed gravity ampere-meter, and (2) a Siemens electro-dynamometer. These were connected in series in several of the trials, and were found to be in perfect agreement. The Evershed instrument had been tested against a Thomson balance.

The consumption of steam in the turbine was measured by passing the feed-water through a measuring tank, the capacity of which I checked. Steam was supplied from an old boiler of the locomotive type, at a pressure of 90lb. to 95lb. per square inch. The steam-pipe was too small, and the loss of pressure between the boiler and the turbine must have been considerable, especially in the full-power trials.

In the full-power trials this boiler was insufficient to supply all the steam, and another boiler was joined to it. It was then impracticable to measure the feed, and the amount of steam passing through the turbine was estimated in these trials by measuring the rise in temperature of the water discharged from the condenser, in conjunction with the amount of the water, as gauged by means of a weir. This rise in temperature

Digitized by Google

and the head over the weir were noted in all the trials, so that when the feed was directly measured a constant was determined which could be applied in cases where a direct measurement of the feed was impracticable.

The boiler was old and leaky, but the amount of water which fell to be deducted from the whole feed on this account was repeatedly determined. The allowances made for leakage are certainly not excessive, and do not in any case affect the full-power trials materially.

The steam required for (1) the feed-pump, (2) the air-pump was supplied by a separate boiler, and is not included in the quantities that are stated below.

The vacuum ranged from 28½in., at light loads, to 26½in. at full load. The temperature of the cold well varied from 5°C. to 18°C.

The trials extended over three days—December 12th, 14th, and 15th, 1891. The turbine was kept running, without change of load, long enough in each case to secure a uniform *régime*, and to prevent any material error from being caused by an inexact reading of the water-gauge glass on the boiler. The machine ran without any hitch, throughout all the trials.

The following are the observed results. The trials distinguished by an asterisk are those in which the consumption of steam was inferred from the rise of temperature in the injection water. In the other trials it was measured directly, as feed-water.

Electrical output in units generated per hour.	Steam used in the turbine in lbs. per hour.	Electrical output in units generated per hour.	Steam used in the turbine in lbs. per hour.
0·3	510 } 492	65·9	2,460*
0·3	475 } (mean)	66·5	2,580
20·8	1,120	93	3,530*
31·2	1,350	100	3,600*
48·5	1,875		

These results are also shown graphically in the accompanying curve, which shows the relation of the number of lbs. of steam used by the turbine per hour to the number of electrical units generated per hour.

It is convenient also to express the results in another way, by stating the number of lbs. of steam used per unit generated, at various rates of output from full load downwards. These quantities, obtained by measurement from the curve, are given in the following table :—

Output in units per hour.	Number of lbs. of steam used per unit.	Output in units per hour.	Number of lbs. of steam used per unit.
10	77½	60	38
20	53	70	37½
30	45	80	37
40	41	90	37
50	39	100	37

It will be seen from these figures that the consumption of steam by this condensing turbine was 37lb. per electrical unit generated, when the machine was giving its greatest output; that the output might be reduced to, say, three-fourths of its greatest value without causing any sensible addition in the consumption of steam per unit; and that at half-load the consumption was 39lb. per unit. When the load is further reduced the consumption per unit increases, as it does in all engines, on account of the work which is expended within the machine itself.

The consumption of 37lb. per unit at full load corresponds to 27·6lb. per electrical horse-power per hour; and the consumption of 39lb. per unit, at half-loads, corresponds to 29lb. per electrical horse-power per hour.

For the sake of comparison it may be added that in a good ordinary compound condensing engine of corresponding power the consumption of steam is usually about 20lb. per *indicated* horse-power per hour, which corresponds (allowing for necessary loss in transmission to the dynamo) to, say, 36lb. per unit. In the special type of single-acting high-speed engines made by Mr. Willans and successfully used in many electric light stations the consumption of steam at full load and at moderately full load is somewhat less. The best results in trials published by him show (with high-pressure and triple expansion) a consumption equivalent to about 30½lb. per unit in a non-condensing engine, and 25lb. per unit in a condensing engine, worked at full load; while at half-load the numbers are about 43lb. per unit and 32lb. per unit respectively.

I have no doubt that if it had been practicable in the turbine tests to use the full pressure of 140lb. per square inch for which the turbine was designed (in place of a pressure of 95lb.) that the consumption of steam per unit would have been considerably reduced.

As they stand, however, the results must be admitted to demonstrate a very remarkable performance. They show that in respect of economy of steam, and therefore of fuel, at full or moderately full load the Parsons' Turbine of the type and size tested now challenges comparison with good engines of the usual kind, while its comparative freedom from friction gives it an exceptionally high efficiency when lightly loaded.

Apart from the question of steam economy, the lightness and compactness of the turbine-dynamo, its small first cost, the perfect ease with which it is started, its freedom from vibration, and the absence of any need for heavy foundations, are points much in its favour of a generator for central-station work.

Mr. Parsons has been good enough to give me every facility for examining the construction of his turbines and dynamos. I see no reason to anticipate that the charges for maintenance, for oil, and for attendance will be larger than in the case of other engines. I should rather expect them to be lighter; and this appears to be borne out by the experience of the Newcastle and District Electric Lighting Company, where turbine generators have been in use for about two years.

I had the advantage of seeing the plant at that Company's station and of obtaining particulars in regard to wages and other items of current outlay from the Superintending Engineer and the Secretary of the Company, who were most willing to supply information.

In regard to first cost, the turbine generator is probably cheaper, in large sizes, than any combination of ordinary engine and dynamo giving equal output. Mr. Parsons quoted to me the following prices for condensing turbines with dynamos, of either the alternating or continuous-current type. The cost of the condensing plant is not included :—

50-unit, £600; 100-unit, £850; 200-unit, £1,300.

The machine tested had an electrical governor which regulated by causing intermittent admission of steam. The action of this governor was not entirely satisfactory, and Mr. Parsons informed me that he meant to substitute for it a modified form of a type of governor which has been found to work well at the Newcastle and District Electric Light Station and elsewhere.

The turbine worked at its full load of 100 electrical units per hour without any sign of distress, and so far as could be judged was capable of giving a greater output without difficulty. The dynamo armature became hotter than is, in my opinion, desirable. This might be avoided by an alteration in the winding of the armature.

With a dynamo wound to give continuous-currents, the consumption of steam in the turbine per electrical unit generated may be confidently expected not to exceed the consumption observed in these experiments.

THE CAUSTIC SODA AND CHLORINE ELECTROLYTIC PROCESS.

Some time since we criticised the prospectus and patent of the syndicate whose name forms the heading of this article, and pointed out what we considered were weak points in the process and loose statements in the prospectus and the report which accompanied it. The process is now being brought into more tangible form, and an experimental plant of fair size has been set up at the works of Messrs. Bowes, Scott, and Western,

Digitized by Google

at Battersea. The principle of the process, like that of many of its predecessors, is the splitting up of a solution of common salt with the production of caustic soda and chlorine by electrolysis, the details for which it claims originality being chiefly those relating to the construction of the anode and porous diaphragm. The experimental plant consists of a set of five tanks, Fig. 1, each with five cells, Fig. 2, with arrangements for circulating the liquor to be decomposed through all the anode and all the kathode cells, the former being of course provided with

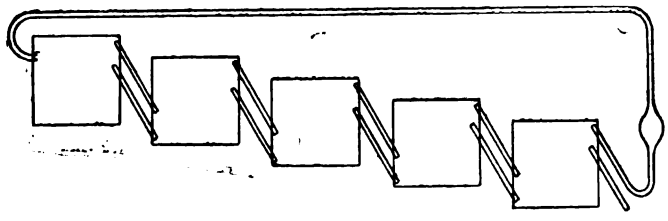


FIG. 1.—Set of Five Tanks.

means for conveying off chlorine and leading it to vessels of the ordinary type for making bleaching liquor or bleaching powder. The diaphragm, as will be seen in Fig. 3, is built up of a number of troughs of glass or slate set in ozokerit, the spaces between them being packed with asbestos. It will be remembered that much was expected of this diaphragm in the early days of the process, and it is true that if it fulfils the claims made for it it will add considerably to the perfection with which the chlorine can

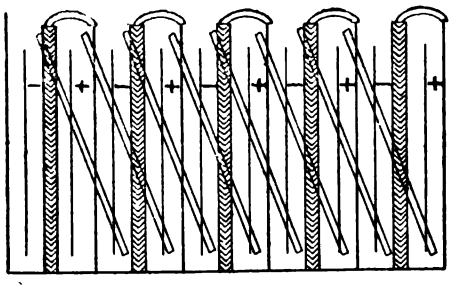

FIG. 2.—Tank consisting of Five Cells, separated by Diaphragms.

be kept out of the kathode cell without at the same time giving rise to much resistance. We may here remark that further information as to the exact resistance of this diaphragm is very desirable. The total resistance of each cell is stated, in the terms to which we objected in our previous article,* as about "5 volts"; but how much of this is due to the resistance of the diaphragm, how much to that of the solution, and how much must be credited to the expenditure of energy necessary to produce caustic soda, hydrogen, and

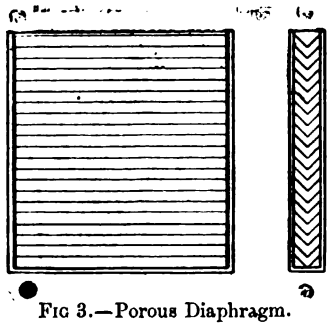

FIG 3.—Porous Diaphragm.

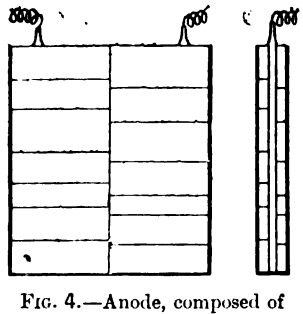

FIG. 4.—Anode, composed of Carbon and Type-Metal.

chlorine from sodium chloride, is left undetermined. With regard to the anode, which we also illustrate, Fig. 4, it consists of plates of retort carbon supported by a core of type metal, connection between the two being established by coppering and tinning the plates before the type metal is cast. It is found that only hard carbon of this description will stand the action of the chlorine; the plates are rendered non-porous by saturation with paraffin wax. They certainly appear well designed for their purpose, and it is stated that they suffer no appreciable deterioration. Turning from the plant to the process itself, it appears that the strength of the salt solution employed may be varied according to the use to which the caustic lye is to be put. Paper makers using 3 per cent. lye and indifferent to the presence of salt, may work with a brine of about 5 per cent. strength, and make no attempt to concentrate the product. If, however, solid caustic soda be required, brine about half saturated may be used with advantage, the caustic liquor boiled down when it reaches a moderate strength, and the salt fished out during evaporation. It is said that owing to the novel diaphragm very little sodium hypochlorite is formed; it is also stated that the chlorine comes away almost perfectly pure, and causes no spurting of the liquor during its evolution. It must be remembered that if the diaphragm is to be efficient the chlorine must encounter no resistance during its passage through the absorbing vessels, and this is provided for by a little exhausting fan capable of lowering the pressure within them sufficiently. At present no attempt is being made to utilise the hydrogen which makes its appearance at the kathode; this means a good deal of waste energy, and appears to have been somewhat overlooked up to the present.

The reports which have been given on the process by sundry experts go to show that an important saving in the cost of caustic soda and bleaching powder should be effected if the calculations on which the estimate is based are verified by the results obtained when working on a large scale. According to our view, the weak point in this, as in other electrolytic processes, is due to the fact that the output is small and slow when considered in relation to the bulky and expensive plant; so that interest on capital thus sunk becomes an item of extreme importance, even should costly repairs be avoided.

Whatever the upshot of the present attempt may be, it has at least been made on a fair scale and with well-designed and workmanlike plant. Power for the whole is supplied by an Elwell-Parker dynamo, capable of an output of about 350 amperes at 22 volts.

EXTENSION OF LOW-PRESSURE NETWORKS.

An interesting little article is contributed by Mr. W. S. Barstow to the *Electrical Engineer* of New York of December 16, 1891, in which he treats of a problem which will some day assume as much importance in London as it has already done in Brooklyn.

"Electric light companies," says Mr. Barstow, "in order to prove that the claim of 'light and power for the public' is justified, find it necessary to enter residential districts, and supply current on the same basis as gas. It is an unfortunate undertaking," he goes on to say, "for any dividend-earning company to erect and endeavour to maintain a central station in a residence district with the expectation of net earnings therefrom during the first or second year. The business man is willing to pay for commercial lighting a sum which he would never think of paying for the lighting of his residence. He will, however, instal 10 lights in his dwelling to one in his place of business, although he may only use one out of the 10. Thus, the lights burning in a residence district are only a small percentage of the lamps installed. The maximum load of a station in a residence district is actually about 25 per cent. of the lamps installed or connected, while that of a station situated in a business section of a city is never less than 50 per cent. This means, that in a residence district we must connect twice as many lights as in a business district to get the same income. Another unfortunate thing in residence lighting is the fact that during four months of the year the dwellings are closed, and during the months they are occupied the light is only used about five hours out of the 24. The fact that current can be supplied more economically from a station already in paying operation than from a station having heavy operating expenses to start with, needs no emphasis, as current generated in quantity with large units working efficiently is more economical than current generated in a number of small units. Thus it only remains to be ascertained

* *The Electrician*, Vol. XXVII., p. 193.

Digitized by Google

what we can afford to lose in conductors. And in order that this point may not be considered entirely theoretically, it might be of value to those interested in this subject to know what has been actually done in this direction from a practical standpoint.

"The second district system of Brooklyn is laid out similar to any ordinary Edison three-wire central-station system of underground conductors; each feeder is brought to a central point of distribution situated on land owned by the company, so that in the event of the load warranting the operating of a station in after years no change in the feeders will be caused by its erection. From this central point of distribution a large feeder is laid to the first district station, a distance of about two miles. The question arose before the work was begun: At what load would the economy of transmission on this feeder be overbalanced by the loss in the conductors and interest on

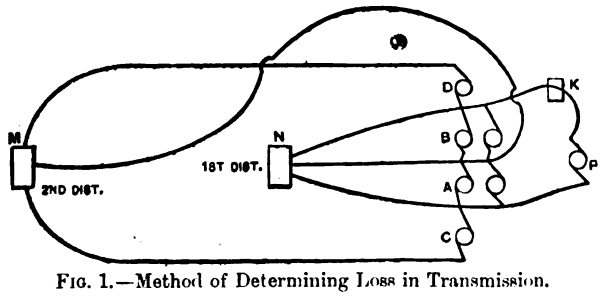

FIG. 1.—Method of Determining Loss in Transmission.

any special apparatus required? To answer this question, the cost of labour, interest on investment, and deterioration of a new isolated station must be balanced against increased cost of labour in old station, interest on investment, deterioration, and the loss in transmission—the cost of fuel, water, &c., remaining the same in either case."

Mr. Barstow then proceeds to show that the problem practically reduces itself to the equation $L - l = \lambda$; where L is the cost of labour per diem at a *new* station, l the increased cost of it at the old station, and λ is the cost per diem of the power lost in the feeder. In the case in question $L - l$ comes out at 42s.

The following plan, similar to the one used by Lahmeyer at Rostock, and alluded to at the time in our editorial columns (*The Electrician*, Vol. XXII., p. 581), was adopted by Mr. Barstow, and has been in successful operation at Brooklyn for the past twelve months.

"In the diagram Fig. 1, M and N denote the centres of distribution of the two districts, in which N is practically the location of one station, and M is about two miles distant from this point. A and B are the two pairs of machines (more or less) on ordinary three-wire system, supplying current at 115 volts to N. To supply current to M (at the same voltage at lamps), dynamos C and D are placed as shown in the diagram. The armatures of these machines C and D are wound for the maximum current supplied to M, the voltage being the maximum economical drop in transmission in feeder. These two machines are belted to a 230-volt motor, P, which is run from the main station bus. As may be seen in Fig. 1, C and D will generate whatever watts are lost in transmission in conductor to M, the watts furnished to the lamp at M being generated at A and B. In fact, in action, C and D are nothing more than electrical (hydraulic) rams raising the pressure of the current delivered by A and B. By making C D series machines they become entirely automatic in regard to the regulation of the pressure necessary to counterbalance the drop in the feeder. In the motor circuit a meter is placed at K, and this gives us the total loss in transmission + the inefficiency of the transforming device, and by subtracting the latter from the total reading the actual loss in the conductor may be obtained. In transmitting 300 amperes to M, the average day load in the residence district, the pressure of C or D is 10 volts."

With this arrangement the average value of λ per diem came out at 13s. 6d., which leaves a margin of about £500 per annum in favour of the long-feeder plan.

"By calculation of total number of lamp-hours (of 8,000 lamps connected) and receipts, the cost per lamp hour at the centre of distribution in the new district two miles from the generating centre is 10 per cent. more than at the generating centre. The above figures need no explanation as to the financial efficiency of low-tension transmission. Of the 8,000 lamps connected 5,000 are located 2,500ft. from the distributing point of this district, or about two and a-half miles from the generating point; 1,000 lamps and 60 H.P. in motors are connected 5,000ft. from the distributing point, or three miles from the generating point!

"Fig. 2 is a diagram of an average daily pressure at the main station-end of the transmitting feeder. The constant for this diagram is 7·82 amperes = 1 volt drop (each volt above 117). This gives one-half the load of the feeder at 117 volts. In the manner above shown, new districts may be entered without serious loss in earnings, and whenever the district becomes so loaded as to pass the point of economy by transmission, a station can be erected which from the very start will have a good paying load. The feeder may then be turned into new territory, or left as a tie-line between the two stations. The advantages of this system for residence lighting will be appreciated by all companies who have struggled along, turning over the net earnings of one station to make good the deficit of another."

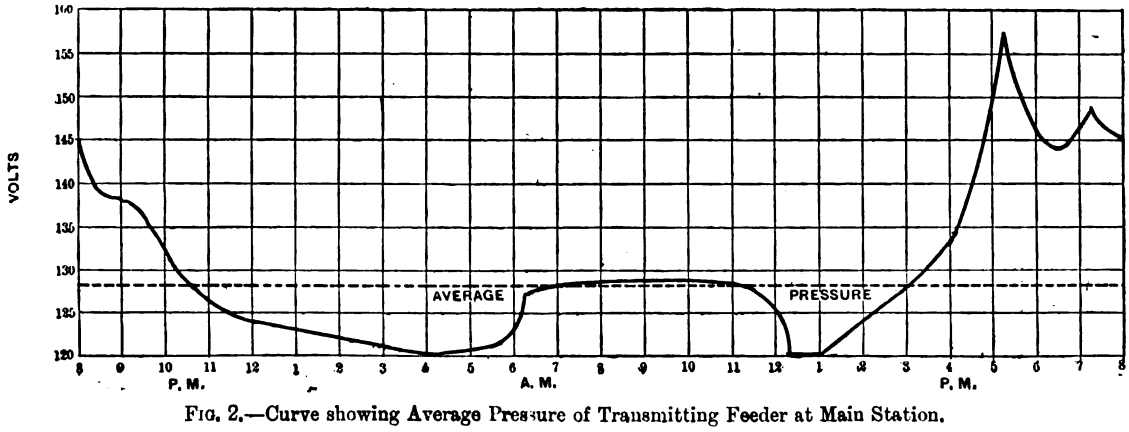

FIG. 2.—Curve showing Average Pressure of Transmitting Feeder at Main Station.

A TELEPHONE TRANSMITTER WITHOUT ELECTRODES.*

BY CHARLES CUTTRISS.

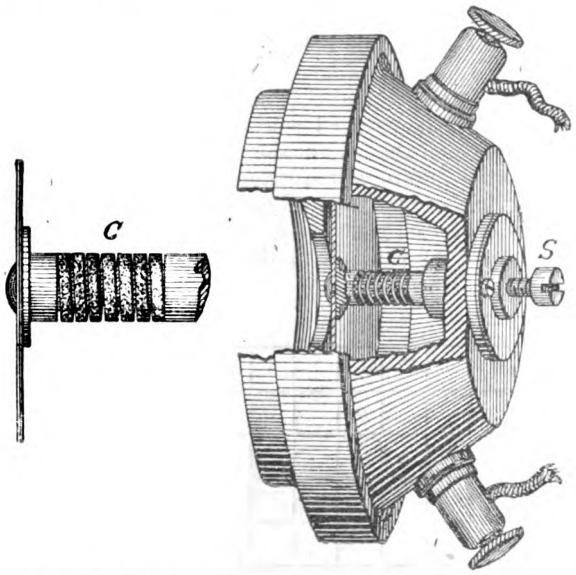
While it would appear that the field of telephone transmitters had been pretty thoroughly gleaned, still among the stubble there has remained one that promises to be of considerable importance both for long and short distance transmission. As is often the case, the present invention is the result of research in a new direction. Upwards of a year ago I was experimenting with some carbon contact points,

* From *The Electrical Engineer* of New York.

Digitized by Google

with a view to getting data of their action under different pressures and with various strengths of current. In one set of experiments I was surprised to observe a steady movement of the galvanometer, indicating a gradual increase of resistance in the circuit; and, as the opposite effect was expected, I was led to examine closely into the cause of this action. Arranging the contact points in such a manner that they could be examined by a powerful magnifying glass, it was observed that on the first application of the battery there was a good surface contact between the carbons, but that as they expanded under the heat the surface gradually became raised until, at last, the contact was so exceedingly small that it became incandescent for an instant. At the moment of incandescence the contact points fell together again, and the action was repeated, the whole cycle taking about 30 seconds, and in some cases it would keep on repeating with great regularity for 20 minutes, or more, before the points became so much changed as to stop the action. While it was interesting to observe this action, it was, on the other hand, very disappointing, as it showed the impossibility of using the contacts for the purpose intended.

I was then led to try a number of contact discs, but here I was met by the difficulty that with the light pressure I was using—only from 2 to 10 grains—the various discs would never resume their former condition after the removal of the pressure. It was at this time that I realised that the only



Figs. 1 and 2.—Cuttriss' Telephone Transmitter without Electrodes.

way to get around the two difficulties would be to make such an arrangement that each contact should have a tendency to spring open, and at the same time preserve continuity of circuit. After trying numerous devices without success it occurred to me that a helical carbon spring, if such a thing could be made, would offer the best solution of the difficulty.

For upwards of a month I had a maker of incandescent lamps trying to produce some of these helices, but without success. I then determined to try it myself; so, with an Edison fan motor geared direct to a fan rigged up out of a tin can, an improvised Fletcher's blow-pipe, and a small circular crucible furnace, I went to work, and in a few hours had got my first helix. But, as may be imagined, it was too ethereal for the rough and tumble of this world.

Nevertheless, it showed that I was on the right track, and after a few days' practice little trouble was experienced in turning out about anything I desired. I now have the carbon helices of such resistances that when closed in their natural condition they have a resistance of about 10 ohms; but when fully distended the resistance is upwards of 500 ohms, and a movement of ·01 of an inch tending to open the convolutions makes a variation of from 100 to 200 ohms. Their action on the instrument for which they were designed was perfect, and no sparking could be observed between the convolutions until the battery was increased to such an extent that the whole helix was heated to some 300 or 400 degrees Fahrenheit.

This absence of sparking under heavy battery at once struck me as a valuable feature in a telephone transmitter; and as the battery circuit could never, under any circumstances, be interrupted, there should be an absence of those ear-breaking kicks which are so often experienced when impatience is expressed at the distant end.

As a result I devised the simple arrangement shown in the accompanying engravings. As will be noted in Fig. 1, the helical carbon spring C is permanently cemented to the diaphragm and presses against the end of a screw, S, to which it is also permanently connected and by which its tension can be regulated and the convolutions of the helix brought nearer together, or separated, as desired. The carbon helix is shown enlarged in Fig. 2.

Experiments proved the correctness of my theory, and not only does the instrument transmit speech loudly, but the enunciation is so remarkably clear that I have been led to look for some particular reason why this should be so. I think it will be found to be owing to the extreme lightness of the helix (generally less than one grain); to the absolute continuity of the circuit—that is to say, the elimination of electrodes; and also to the fact that as each part of the spiral is tending to open itself it absolutely precludes any tendency for the surfaces to jam or lock together.

DAMPING OF ELECTRICAL OSCILLATIONS ON IRON WIRES.*

BY JOHN TROWBRIDGE.

It has generally been assumed by those who have studied the subject of very rapid oscillations of electricity, such as occur in Leyden-jar discharges, that the magnetic character of the conductor has very little influence on the nature of the discharge. The early investigations of Hertz seemed to show that for such oscillations the self-induction of the electric circuit depended only on the size and shape of the conductors, being independent of the material; and the analogous researches of Dr. Lodge appeared also to point to this conclusion.

Although the impulsive impedance is apparently not affected by the magnetic character of the wire, our experiments lead us to believe that discharges of the quick period of a Leyden jar are affected very appreciably by the magnetic nature of iron, steel, and nickel conductors. This effect is so great that it damps the electrical oscillations, and makes it difficult to determine whether the time of oscillation is also affected by the permeability of the conductor.

The apparatus employed was similar to that described in my investigations of electrical oscillations with an air condenser (*Proc.* American Academy of Arts and Sciences, May 28, 1890). Certain important modifications, however, were made. The plane mirror which I used in the former research was replaced by a concave mirror of 10ft. focus and 3½in. in radius. This mirror was mounted upon the end of the armature shaft of a one-half horse-power electric motor.

The discharging apparatus consisted of a sharp-cutting tool, insulated, and mounted on the edge of the rotating disc bearing the mirror. It was metallically connected with a grooved ring of brass mounted upon the shaft and insulated from it by hard rubber Around this was wound a copper wire, one end of which was connected with the discharging wire and the other drawn taut by a rubber band. The electrical discharge was thrown upon the circuit by pushing forward a lever, which brought a solid hinged frame containing a strip of soft type-metal into contact with the rapidly revolving steel cutting tool. An electrical contact was thus insured by the tool cutting a groove in the strip of type-metal. In order to avoid a spark at the contact the type-metal was thickly covered with a wax of peculiar composition. The only spark, therefore, that occurred was the one the oscillations of which I desire to study. At each trial the type-metal was moved so as to expose a new cutting surface. The type-metal was insulated from the rest of the apparatus, but connected with the outer coating of the Leyden jar. First, both terminals of the Holtz machine were thrown off, and immediately after, the cutting tool, ploughing its way through the type-metal, placed the outer coating of the Leyden jar in circuit with one of the two parallel wires leading to the terminals of the spark. The other wire was permanently in connection with the inner coating of the jar.

Besides the short lead wires above described, the discharging circuit consisted of two parallel wires 30 centimetres apart and

* From the *Phil. Mag.*, December, 1891.

Digitized by Google

510 centimetres long. These were the only portions of the apparatus changed during the experiment, and they were replaced by wires of different material and of different size. The other conditions—length of spark, lead wires, and the copper cross-wire connecting the outer ends of the long parallel wires—remained undisturbed throughout the experiment.

The Leyden jar was charged each time as nearly as possible to the same potential, judging by the number of turns given the Holtz machine. It is unfortunate that no more accurate means of measuring it were at hand, although the different negatives showed but slight variation. The capacity of the jar with alternations of this period was 5,060 electrostatic units.

I describe the discharging portion of the apparatus minutely, for the success of an investigation of this nature depends upon the suppression of all sparks save that which one wishes to observe, and my method surely and completely accomplished this. The photograph of the spark could thus be made to fall very accurately on the sensitive plate. When one considers that the image of the spark was flying through the air on a circle of ten-feet radius with a velocity of a mile a second, it will be seen that an extremely small deviation in the point of contact between the cutting-tool and the type-metal would have thrown the image entirely off the sensitive plate. A singular phenomenon was noticed in this connection. When a comparatively low potential was used, such as that afforded by the air-condenser used in our previous investigation, the cutting-tool ploughed two or three millimetres along the surface of the type-metal before a spark passed at the point in the circuit where it was desired. With higher potentials this phenomenon was also observed, but the extent of cutting was diminished. It is possible that the insulating wax may have melted under the sudden blow of the cutting-tool, and, flowing around it, prevented instant contact. This seems to me improbable, for a deep and clear-cut groove was made in the soft type-metal. Great attention was paid to the solid structure of this contact apparatus. It was entirely separate from the support of the revolving parts, and was perfectly steady.

The other end of the armature-shaft was lengthened into a cylindrical chronograph, similar to that described in the article already cited, and its performance left nothing to be desired. A small Ruhmkorf coil excited by two storage cells, and interrupted by a seconds pendulum, gave a record of the speed of the mirror. The stylus which drew the spiral turns on the barrel of the chronograph was drawn along the barrel by means of a small heavily loaded carriage, which, on being released at the moment the lever arm threw the type-metal in contact with the cutting-tool, descended an inclined plane of adjustable height. A small Toepler Holtz machine charged a large Leyden jar, and it was found to work admirably in all states of the weather.

The apparatus which I have thus described was the result of the experiments of the previous year, and worked for months without failure; and the taking of photographs of the oscillating discharge by it became a mere matter of routine.

The following cases were tried :—

1. When the long parallel wires were of copper (diameter ·087 centimetre), the number of double oscillations visible on the negatives averaged quite uniformly 9 or 9·5.

2. Where the wires were of German silver (diameter ·061 centimetre), 3 oscillations were visible.

3. But when an annealed iron wire (diameter ·087 centimetre) was substituted, only the first return oscillation was distinctly visible, with occasionally a trace of the first duplicate discharge.

4. On substituting fine copper wire (diameter ·027 centimetre), 5 complete oscillations were quite uniformly visible.

5. Fine German silver wire (·029 centimetre), nickel wire (·019 centimetre),* soft iron (·027 centimetre), and piano steel wire (·027 centimetre), gave but faintly the first return discharge after the pilot spark.

The pilot sparks were in all cases strong.

The single return discharge through the iron wire did not admit of measurement sufficiently accurate to furnish any basis for calculation of self-induction. The time did not apparently differ, if at all, by more than 14 or 15 per cent. Some general reasoning based upon the number of oscillations may be of interest. It must be acknowledged, however, that this reasoning is open to criticism, although it affords the most plausible explanation of the phenomenon. The phenomenon itself is not a doubtful one.

The time of a double oscillation for the large-sized copper wire was ·0000020 second, for the small copper wire ·0000021 second. The others, as far as could be determined, did not differ much from these values, and for this purpose either value is sufficiently accurate. Denote by R′ the ohmic resistance of the parallel wires to alternating currents of this periodicity, by R the resistance to steady currents.

$$p = 2\pi/t = 3{,}000{,}000 \text{ (practically).}$$

* Obtained by the kindness of Joseph Wharton, Esq., of Philadelphia,

Taking the cases up in order :—

1. Large copper wire,

$$R = \cdot 285 \times 10^9,$$

and substituting in Lord Raleigh's formula

$$R' = \sqrt{\tfrac{1}{2} p l \mu R},$$

$$R' = \cdot 66 \times 10^9.$$

2. Large German silver wire,

$$R = 9 \cdot 21 \times 10^9,$$

and substituting in the series

$$R' = R\left(1 + \frac{1}{12}\frac{p^2 l^2 \mu^2}{R^2} - \frac{1}{180}\frac{p^4 l^4 \mu^4}{R^4} + \ldots\right),$$

$$R' = 9 \cdot 2 \times 9.$$

3. Large iron wire,

$$R = 2 \cdot 5 \times 10^9,$$

and if there is a true time lag, as often stated, such as to prevent action of the magnetic property of the iron, and if on this assumption we make $\mu = 1$,

$$R' = 2 \cdot 78 \times 10^9.$$

4. Fine copper,

$$R = 3 \cdot 3 \times 10^9,$$

$$R' = 3 \cdot 5 \times 10^9.$$

5. Again, as before, call $\mu = 1$ in iron, nickel, and steel.

The length of these circuits was 7·41 metres, the remainder of the 10·20 metres—2·79 metres—being of copper wire of R′ = ·94. The value of R′ in the separate cases, including in each the resistance ·94 of the copper portion, was as follows :—

Soft iron..... $15 \cdot 0 \times 10^9$,
Piano-steel... $20 \cdot 7 \times 10^9$,
Nickel..... $30 \cdot 6 \times 10^9$,
German silver $23 \cdot 0 \times 10^9$.

The ratio of the strengths of successive discharges during the oscillation is given by the function

$$\epsilon^{r\,T/2\,L},$$

where r is the ohmic resistance, T the time of a double oscillation, and L the self-induction. The ratio of one discharge to the nth one after it is

$$\epsilon^{n\,rT/2L}.$$

If we assume—and it is a large assumption, but one which, perhaps, the result will in some measure justify—that the ratio of the strength of the first to the strength of the last visible discharge is more or less a constant, we may make use of the above data. Denote T/2 L by A, and call the unknown resistance of the short connecting lead wires and of the spark x. Then will $r = R' \times x$; n will be the number of complete oscillations visible.

Take cases (1) and (2), large copper and large German silver wires,

$$\epsilon^{n_1 (R'_1 + x) A} = \epsilon^{n_2 (R'_2 + x) A},$$

$$n_1 (R'_1 + x) = n_2 (R'_2 + x),$$

$$9 \cdot 5 (\cdot 66 + x) = 3 (9 \cdot 2 + x),$$

$$x = 3 \cdot 4 \text{ ohms.}$$

Taking cases (1) and (4), large copper and small copper, similarly,

$$n_1 (R'_1 + x) = n_4 (R'_4 + x),$$

$$9 \cdot 5 (\cdot 66 + x) = 5 (3 \cdot 5 + x),$$

$$x = 2 \cdot 6 \text{ ohms.}$$

Experiments with other copper wires having R′ equal to 3·4 and 1·27 gave 5 and 8 for the values of n respectively, or $x = 2 \cdot 4$ ohms.

The resistance (R′) of the lead wires forming part of x was ·8 ohm, leaving as a possible value for the resistance of the spark about 2 ohms.

If, taking this value of x, we calculate the value of R′ necessary to damp out the oscillation in one complete double discharge in the case of the large iron wire, we shall have

$$9 \cdot 5 (\cdot 66 + 3) = 1 (R' + 3),$$

$$R' = 30 \text{ ohms.}$$

But neglecting the magnetic property of the iron, its calculated resistance to alternating currents of this periodicity was R′ = 2·78 ohms. This is obviously inadequate, and would point to the conclusion that the oscillation is not, as sometimes stated, too rapid to admit of the magnetic action of the iron.

If we substitute this value R′ = 30 in the equation

$$R' = \sqrt{\tfrac{1}{2} p l \mu R},$$

we have for the resulting value of the magnetic permeability

$$\mu = 230.$$

Digitized by Google

This lies between the limits $\mu = 103$ and $\mu = 1110$, found by taking the number of oscillations one and a-half and one-half respectively for the case of the iron wire.

It should be noticed that this estimate of μ necessitates assuming that T and L remain the same within broad limits. Measurements of the single oscillation on the negatives show that this is near enough the case. Part of the more rapid decay of the oscillation in the iron may be well ascribed to the dissipation of energy by hysteresis. While we cannot place much reliance upon an estimate of its value in such a case—its percentage effect probably increasing rapidly with the decay of the spark—it is not difficult to show that its influence may be very great.

There still remains the fact, not generally recognised, that in Leyden-jar discharges through iron wires the magnetic property of the iron has time very materially to modify the character of the spark.

I give an example of the measurement of the half oscillation, which was the only one visible on the photograph of the discharge over iron wires, all the others having been damped or extinguished by the iron, in comparison with the measurement of the similar half oscillation on copper wires of the same diameter as the iron wires. The number of oscillations on the copper wires was from eight to ten. The total duration of the discharge on iron wires was only three-millionths of a second, while that on similar copper wires was three hundred-thousandths of a second. A steel wire gave the same results as the annealed iron wires.

	Length of first half oscillation in millimetres.		Length of first half oscillation in millimetres.
Fine iron wire.	·23 ·21 ·19 — ·21	Large iron wire.	·20 ·20 ·19 — ·19
Fine copper wire.	·19 ·20 ·20 — ·19	Large copper wire.	·17 ·18 ·20 — ·18

I wish to express my deep obligations to my assistant, Mr. W. C. Sabine, for his valuable suggestions and for his skill in the mechanical details of this investigation.

Conclusions.

1. The magnetic permeability of iron wires exercises an important influence upon the decay of electrical oscillations of high frequency. This influence is so great that the oscillations may be reduced to a half oscillation on a circuit of suitable self-induction and capacity for producing them.

2. It is probable that the time of oscillation on iron wires may be changed. Since I have been able to obtain only a half oscillation on iron wires, I have not been able to state this law definitely.

3. Currents of high frequency, such as are produced in Leyden-jar discharges, therefore magnetise the iron.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

New York, *December* 24, 1891.

The Edison Electric Traction System.—At last an authoritative statement has come from the Edison General Electric Company regarding Mr. Edison's new plan for a street railway service, of which there has been so much talk. It proves to be precisely what my first mention of it to you indicated—his old plan of supplying a very low E.M.F. to the rails, furnishing the current to short independent sections of track by means of constant-current transformers operated at high tension from a central station. It is stated that the car motors are wound with uninsulated copper wire, and that the pressure is so low that the armatures themselves can be doused with water without the slightest ill effect. The Edison Company was presumably driven in self-defence to make this frank statement of the facts, because the reports that went the rounds were of such a character as to seriously hinder the development of the trolley system, in which the Edison Company, like others, is interested. The opinion of electrical engineers in general seems to be unfavourable to this plan, as, aside from its involving the reconstruction of all tracks, and a most elaborate system of bonding in order to carry these enormous currents, its efficiency is necessarily low on account of the extra transformation required and the inevitable leakage, which, although it would be only a few horse-power per mile, is still very objectionable.

The Trolley System in Brooklyn.—A great victory has been achieved for the trolley system in the city of Brooklyn, where the Board of Aldermen recently passed an ordinance permitting its use upon the surface roads. The Company that controls the street railways of Brooklyn has long been desirous of changing from horses to electricity, but until now they have been hindered by the difficulties in obtaining the necessary permission. Now, however, the work will probably be begun next spring, and carried on as rapidly as possible. The intention of the Company as regards the system of motors to be used has not been made public; there seems, however, to be a strong probability that the Thomson-Houston Electric Company, which furnished the equipment for the great West End system of Boston, will be looked on with special favour. Possibly, too, some one of the new gearless motors will be given a chance to show its merits. It is safe to say, though, that the bulk of the equipment will be single-reduction machines, as these seem to be now the general favourities, and have already proved their merit.

Proposed New Edison Station for Chicago.—It is rumoured that Chicago is to have an Edison central station of enormous capacity, quite eclipsing anything of the kind in the world; and it is even stated that the site has been selected for it. Chicago, in the compactness of the business district, is favourably situated for low-tension electric lighting, and the Edison Company has already made a good record.

Telephones.—The telephone interests have been pursuing their quiet way, quite undisturbed by the cyclone of patents that struck the business a few weeks since. The long-distance service in and about New York is constantly on the increase, and is, on the whole, unusually well conducted. It is the intention ere long to use double metallic circuits throughout the city.

CORRESPONDENCE.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

Sir: Will you allow me to point out what I consider a flaw in your ingenious answer to Mr. Gerald Molloy's analogy. It is quite true, as you say, that the *pounds*, in foot-pounds, do not represent mass, but *force*, and so are not analogous to *quantity* of electricity. But neither, on the other hand, do the *feet* correspond to volts. If, instead of comparing the formula $W = Q \times V$, with $W = M g \times h$, we compare it with $W = M \times g h$, the analogy is exact. Q corresponds with M, and V with g h, which latter is the difference of potential due to difference of level; whereas h is the difference of level itself.—Yours, &c.,

Wimbledon, Jan. 2, 1892. W. M. Madden.

P.S.—It does not follow that Mr. Molloy's analogy is conclusive. Analogies seldom prove anything; and when, as in this case, the definitions are founded on the analogy, it is clear that the latter can afford no extraneous support to the former.

THE ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: In your issue of December 4th appears an article by Mr. O. Heaviside in which, after advocating the use of vectors, the author mentions the Association for the Improvement of Geometrical Teaching, but states that he has no knowledge of its work. With your permission I will give a short sketch, in the present letter, of the *history* of the Association, and in a second one of *its present condition* and *its aims for the future*.

Digitized by Google

The Association held its first annual meeting in January, 1871, with Dr. T. A. Hirst in the chair. In an able address, which still deserves the careful study of geometrical reformers, the President pointed out both the urgent need of reform and the great practical difficulties in the way of effectively carrying it out. Among the resolutions carried was the following important one, from which most of the subsequent work of the Association has sprung :—"*That all members be invited to furnish programmes, or suggestions relative to a programme, of the subjects which a text-book on Geometry ought to include.*" In response, eleven members sent in programmes. In these there was entire coincidence on eight important points, and great agreement on six others.* It was now felt that the Association could proceed with the formation of a Syllabus of Geometry, and a sub-committee was appointed with that object. After considerable communication of ideas between members of the Association and various eminent mathematicians, a Syllabus was drawn up and finally adopted by the Association at its fifth annual meeting (1875). This Syllabus was submitted to various important bodies, one of which, a committee appointed by the British Association *for the purpose of considering the possibility of improving the methods of instruction in Elementary Geometry*, and including among its members Profs. Cayley, Sylvester, H. J. Smith, Henrici, and Clifford, reported favourably on the "care and the regard to the essential conditions of the problem" with which it had been drawn up.

The next step was to publish a Text-Book ; for until that step had been taken the want of a suitable one was an ever ready answer on the part of obstructive examining boards when asked to give consideration to the work of the Association. The completion of the Text-Book in 1886 afforded a convenient occasion for memorialising the Universities ; and in answer to a numerously signed petition the Oxford Board of the Faculty of Natural Science reported as follows :—

"That a rigid adherence to the ordinary text-books of Euclid should no longer be insisted on, but that a greater freedom of demonstration should be allowed, both in Geometrical teaching and in Examination.

"That, nevertheless, Euclid's *method* should be required in all Pass Examinations in Geometry, in so far as that no axioms other than those of Euclid shall be admitted, and that no proof of a proposition be allowed which assumes the truth of any proposition which does not precede it according to Euclid's order."

This report was adopted by the Hebdomadal Council (June 20, 1887), and the report, to the same effect, of the Cambridge Special Board for Mathematics was adopted by the Senate, March 8, 1888.

The Council of the Association then addressed Her Majesty's Civil Service Commissioners, calling attention to the action of the Universities, and received a reply that they had "instructed their occasional examiners to make no deduction from the marks allotted to a question because a candidate substitutes another proof for Euclid's if this proof is a sound one and keeps to Euclid's sequence of propositions." As far as Geometry is concerned, though doubtless many improvements still remain to be effected in the methods of teaching it, the Association seems to have carried out the corporate aims with which it started, *as far as is desired by the greater part of those teachers who compose it.*

I hope to devote a second letter to its present condition and to the work that lies before it, merely drawing attention to the fact that in 1881, without altering its *name*, the Association extended its work so as to include all branches of Elementary Mathematics and Mathematical Physics.—Yours, &c.,

EDWARD M. LANGLEY, Hon. Sec. A.I.G.T.

16, Adelaide-square, Bedford.

*P.S.—The eight points on which there was entire agreement were :—

(*a*) That practical geometry should precede theoretical.

(*b*) That numerical examples should be introduced in illustration.

(*c*) That the axiom known as Playfair's respecting parallels, viz., "Two straight lines which intersect one another cannot both be parallel to a third straight line," should be substituted for Euclid's.

(*d*) That the notion of rotation should be introduced into the definition of an angle.

(*e*) That Euclid's treatment of regular figures in Book IV. is unsatisfactory.

(*f*) That the treatment of proportion for both commensurable and incommensurable quantities should be rigorous.

(*g*) That problems should be separated from theorems.

(*h*) That the conception of a Locus should be introduced.

The six points on which there was great, though not entire, agreement :—

(i) That it should be considered as an axiom that the shortest distance between any two points is the straight line joining them.

(ii) That the treatment of parallels should precede that of the comparison of triangles.

(iii) That the restriction of the term "angle" to such angles as are less than two right angles should not be maintained.

(iv) That the method of superposition should be more freely used than in Euclid.

(v) That in the treatment of a tangent the method of limits should be recognised from the outset.

(vi) That Euclid III., 35—37, should be proved by similar triangles.

PLATINOID v. COPPER FOR D'ARSONVAL GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR : Replying to Mr. Crawley's letter on the above subject, published in your issue of December 18, 1891, I had no desire to debit him with hanging a 0·4-ohm coil with a 10-ohm suspension ; for I am well aware that he understands the subject too well not to utilise Prof. Ayrton and Perry's phosphor bronze strip in such a case. The comparison of a 10-ohm platinoid coil and a 0·4-ohm copper one was made merely to show that in cases where it is desirable to use instruments of comparatively low resistance (and these cases are of frequent occurrence), a comparison made on the lines he had chosen for the 500-ohm platinoid and the 20-ohm copper, viz, equal numbers of turns of the same gauge of wire, was by no means as favourable to copper as in the example he had chosen. The difference arises from the fact that the resistance of the suspension then becomes so important.

A better basis of comparison in such cases was then described (*see* §§ 6, 7, and 8 of my previous letter, *The Electrician*, p. 154), and to this I have nothing to add.

Mr. F. V. Andersen's letter calls for more detailed considerations.

First of all let me say that he evidently misunderstood Prof. Ayrton's remarks about the improvements introduced by the writer. The increased sensitiveness to which Prof. Ayrton referred is of the order 3 or 4, and not 20 times. On the other hand, an instrument, in designing which Prof. Ayrton and the writer are at present engaged, promises an increase of sensitiveness of between 100 and 200 times that of an ordinary d'Arsonval galvanometer.

Coming to the main point at issue, viz., whether it is desirable to replace the 420-ohm copper coil of his standard ammeter galvanometer with a 10-ohm platinoid one, Mr. Andersen pleads that the all platinoid instrument would be useless for the special purposes referred to in the Paper by Capt. Sankey and himself. On looking over that Paper the only purpose to which the instrument seems to be applied, other than as a shunt to the main ampere-rheostat, is to calibrate the standard voltmeter galvanometer. Here the "current galvanometer" is put in series with a Clarke's cell, and is used to indicate any want of balance between the E.M.F. of the cell and the potential difference at the terminals of rheostat A. According to the Paper the spot of the present instrument will move visibly for a ten-millionth of an ampere, and this corresponds

Digitized by Google

to an error of 0·011 per cent. in the calibration of the voltmeter. If we now suppose the copper-wound coil replaced by the one wound with platinoid, the same movement would be caused by a current of

$$1/10 \times 21{\cdot}5 \times 4/5 \times 10^{-6} \text{ amperes,}$$

i.e., by 1·72 millionths of an ampere.

Since the resistance of the circuit would be 410 ohms less than when the copper coil was used, the percentage accuracy attainable with the platinoid coil would be

$$\frac{0{\cdot}011 \times 17{\cdot}2\,(1600 - 410)}{1600}$$

or 0·14 per cent., which is well within the 0·2 per cent. aimed at by the authors.

But I venture to think that the accuracy attainable with the copper coil has been considerably understated; for, from Table 2 of the Paper the ratio between the second and third constants (K) is 5 to 1; and since the accuracy attainable is $\frac{1}{5}$ per cent., a deflection of a fifth the length of the scale can be read to an accuracy of $\frac{1}{5}$ per cent. This corresponds to 0·44 scale division, and hence means a current of $0{\cdot}026 \times 10^{-6}$ amperes; therefore the accuracy attainable is 3·8 times that stated, consequently it would be possible to detect an error of 0·0029 per cent. ($\frac{1}{340}$ per cent.) with the copper coil. Making a corresponding correction for the platinoid coil, it would enable the balance to be kept within 0·037 per cent. ($\frac{1}{26}$ per cent.).

The above numbers show that the platinoid-wound instrument would be amply sensitive for calibrating the standard voltmeter; and, so far as this test is concerned, the substitution of a 10-ohm platinoid coil for the 420-ohm copper one would not necessitate an extra galvanometer being installed. Hence Mr. Andersen's "Disadvantage No. 1" does not exist.

It is no use calibrating an instrument to an accuracy immensely greater than that to which its scale can be read. Extreme accuracy in calibration seems to be particularly unnecessary in the case of the standard voltmeter; for, although the authors say that in calibrating it an error of 0·011 per cent. could readily be detected, yet (as was pointed out by Prof. Ayrton in the discussion on the Paper) in using the instrument with constants 0·05, and 0·1 (Table 2), errors amounting to 0·4 per cent. are neglected. These errors arise from the fact of the resistance of the galvanometer circuit not being very large when compared with that of the shunted coil of the potentiometer.

The second disadvantage Mr. Andersen mentions, viz., increased heating of the resistance coils, turns out to have no practical existence; for even with the larger currents required by the platinoid coil, the heating is so small as to make no appreciable error, even if the maximum current is kept passing for many hours. This will be proved by the calculations which follow; but before proceeding with them I may point out that the current in the platinoid coil, to give a deflection across the ampere scale, is not, as stated by Mr. Andersen, 21·5 times as great as that required by the copper coil, but in reality 17·2 times that value. However, the heating is so insignificant that one can well afford to assume that the platinoid coil requires 21·5 times as much current as the copper one; and to make the comparison as unfavourable as possible for the platinoid coil, I will make this assumption. It should also be observed that the number of ohms to be put in series with the platinoid coil will only be 1/21·5 of those required with the copper coil; hence, although the heat generated in a coil of a particular resistance will be 462 times as great, yet the total heating will be only 21·5 times as great.

It also follows that 1,000 ohms will be more than sufficient to put in series with the platinoid coil, and consequently the highest value for any single coil will be 400 ohms. This coil being of the highest resistance would be wound with finer wire than the rest of the coils; and since all the coils carry the same current, the heating in the 400-ohm coil will be greater than in any other. If, therefore, it can be shown that the heating of this coil is unimportant, still less important will that of the other coils be.

The power spent in a coil of resistance R is $C^2 R$ watts.

In the case under consideration $C = 1419 \times 10^{-6}$,

and $R = 400$

$$\therefore \text{ watts} = \left(\frac{1419}{10^6}\right)^2 \times 400$$

$$= 0{\cdot}000805.$$

This reduced to calories (water gramme C°) gives

0·000194 calories per second,

or, 0·7 calories per hour.

Now, the wire on a 400-ohm coil (taking Messrs. Elliott's ordinary G.S. boxes as basis) will weigh about 2oz. (56·7 grammes); and, since the specific heat of platinoid is about 0·09, this gives a water equivalent of 5·1 grammes.

To find the actual rise of temperature of such a coil when a current of 1,419 micro-amperes had been passing through it for a given time, one would require to know many conditions; but to simplify matters, and to make the case as bad as possible for platinoid, let us assume that all the heat generated in the coil is used in raising the temperature of the metal, and that not a trace of it escapes by radiation, convection, or conduction. On this assumption, the temperature of the 400-ohm coil would be raised 1°C. in 7¼ hours, and to change the resistance of the coil by one-tenth per cent. would necessitate the maximum current being kept on for 32 hours.

It will be evident to all that radiation, &c., would prevent even a change of this small amount ever occurring; hence the larger currents needed by the platinoid coil would never introduce any appreciable error in an apparatus designed to measure to an accuracy of $\frac{1}{5}$ per cent. Mr. Andersen's "Disadvantage No. 2" of platinoid is, therefore, of no practical importance.

His third objection is somewhat more reasonable; for, as he shows, the bulk of metal in the winding is certainly increased. But the total weight (and that is the important point) I shall show is but slightly increased. The bulk of the winding (metal and silk) remains unaltered, but in the copper coil the ratio of silk to copper is about 3 to 1, whilst the ratio of silk to platinoid is 1 to 2·5. The copper frame on which the coils of instruments of the pattern employed at Thames Ditton are wound usually weigh from 4 to 6 grammes (say 5 grammes), whilst the metal in the 420-ohm copper winding is about 0·8 gramme. The silk and varnish may be taken as 0·3 gramme, which gives a weight of 6·1 for the copper coil; that of the platinoid coil would be, frame 5·0, platinoid 2·7, silk, &c., 0·1—total 7·8 grammes. The ratio of the weights is therefore $7{\cdot}8/6{\cdot}1 = 1{\cdot}28$.

Now, the breaking load of a platinoid suspension wire such as is used in the instrument under discussion is about 180 grammes, hence with the heavier coil there is a factor of safety of 23, which is quite large enough for the purpose. Consequently, the small extra weight of the coil introduces no disadvantage on account of stress in the suspending wire, and the only disadvantage it has is to cause the period of oscillation to be slightly longer. For example, if the period is 1 second for the copper coil, it would be 1⅛ seconds for the platinoid one.

Having shown the true nature and importance of Mr. Andersen's "disadvantages," I desire to point out that *the chief advantage* of the platinoid coil is that no temperature correction whatever is required for the galvanometer and resistance coils. Such a galvanometer, combined with rheostat B at Thames Ditton, could be used to measure currents up to 550 amperes to an accuracy of $\frac{1}{5}$ per cent., without any temperature corrections being made. For larger currents the heating of the rheostat would have to be allowed for, but for this only.

A workshop instrument for measuring current, to be satisfactory, should require no temperature corrections of any kind; and this can be attained by using a platinoid-wound d'Arsonval instrument and a platinoid rheostat, designed so that the maximum rise of temperature caused by a prolonged passage of the largest current to be measured does not exceed 5°C.—Yours, &c.,

T. MATHER.

Central Institution, January 5, 1892.

ACCUMULATORS FOR SUPPLY STATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As so much has been said about the inevitable losses which the use of accumulator storage entails on an electric supply system, we think this is a fitting opportunity to enclose the annual report we have just received from the engineer of the Kensington and Knightsbridge Company, which has been our oldest customer, and has continuously used our accumulators for nearly seven years. We give you the figures exactly as received, although they show a low efficiency during last January and February, due to the fact that owing to the exceptionally severe weather the temperature was so low that they were working in an exceptionally unfavourable manner. As soon as means were provided for maintaining the battery rooms at a regular temperature, the efficiency at once rose to the average of the year, viz., 79 per cent. These efficiencies are the actual commercial efficiencies taken at the recording meters; the losses include not only the losses in the batteries themselves, but those due to the resistance of the charging leads which connect the distant accumulator station with the generating station. The losses shown, therefore, are accurately representative of the total losses due to the use of accumulators for that part of the output which passes through them. This at Kensington is one-eighth part of the whole output, so that the use of accumulators in this station during the past year has only entailed the loss of 2½ per cent. of the entire output. Mr. Miller's remarks are interesting in showing that the efficiency obtained from the home batteries, which does not include losses in charging mains, is practically in excess of 85 per cent.—Yours, &c.,

CROMPTON-HOWELL ELECTRICAL STORAGE COMPANY (LIMITED).

Mansion House-buildings, London, E.C., Jan. 24, 1892.

During January no provision had been made at the Queen's Gate battery station for heating, so that the efficiency fell very low.

During March improvements were made in the system of charging the batteries, hence the increased efficiency.

The efficiency in watts cannot be calculated direct from the figures given for ampere-hours, as the results depend upon the proportion of work done by the batteries at each station; owing to the fall of potential in the charging mains to Queen's Gate, the watt efficiency at that station must be lower than at Kensington Court; also it depends on the amount of charging done separately or in connection with the lighting.

A few readings are given, showing the efficiency of the Kensington Court home battery, taken by themselves in order to show how considerably the loss in the charging mains reduces the total average efficiency for the year. (Signed)

H. MILLER, Kensington Court, Resident Engineer.

Proposed Utilisation of the Water of the Radaune.—A project is on foot for utilising power derived from the water of the Radaune. It is proposed to convey the water for some distance in underground tubes, and it is expected that 10,000 H.P. hours will daily be available for distribution in the neighbourhood of Dantzig. The cost of the work has been estimated at £1,000,000.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Offices not later than first post Thursday morning.*]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—The Municipality of Irun, in Spain, invite tenders for the erection of an electric light central station. Particulars may be obtained from the Alcalde, Señor Nicolas Guerendiain, to whom tenders are to be handed at noon on January 20th. Each person tendering must deposit a sum of 19,500 pesetas, which will be immediately returned to unsuccessful applicants.

——— The Bristol Urban Sanitary Authority invite tenders for piling the site of the central electric lighting station at Temple Back, Bristol.

COLONIAL AGENCIES.—We have received a letter from Messrs. Thomas T. Draper and Co., of Melbourne, notifying their ability to accept agencies for electrical plant and apparatus in Australia, and they offer any house wishing to do business with them satisfactory bank references in London.

ALMANACKS AND DIARIES.—We have received a paper-knife from the Eastern Telegraph Company, on the handle of which there is an calendar for 1892, the blade bearing a map of this Company's cable system and connections.

——— From Crompton and Co. (Limited) we have received a neat little de la Rue "Thumb" condensed diary, giving some particulars with regard to Crompton dynamos, motors, and arc lamps.

——— The staff of the Commercial Cable Company have sent us a handsome Christmas and New Year's Card, in the shape of a well-executed photogravure of the repairing ship "Mackay-Bennett."

PRITCHETT BROTHERS.—We are notified that Mr. G. E. B. Pritchett, of 1, Hanway-place, Oxford-street, W., has taken into partnership his brother, Mr. T. W. Pritchett, and that the firm have removed to 31, Soho-square, W., where business will be carried on in future under the title of Pritchett Brothers.

CHARLESWORTH, HALL, AND CO.—We are informed that Messrs. Appleton, Burbey, and Williamson, of 92, Queen Victoria-street, E.C., have been appointed London agents to Messrs. Charlesworth, Hall, and Co.

CATALOGUES AND INFORMATION WANTED.—A correspondent writes us as follows: "On behalf of a foreign Government I beg to ask, through your columns, for catalogues and for illustrated matter of systems and machinery for telegraphs (land and submarine), telephones, lighting by all systems, obtaining power from waterfalls, and any good chemical applications of electricity to tanning and similar processes, also relating to instruments of precision for military and naval purposes. English language preferred. Being only an agent, it is useless to call on me. Details will be gone into hereafter." Our correspondent is known to us, and if those of our readers who can assist him in getting this information together will address their communications to the Publisher of *The Electrician*, care shall be taken that the communications, printed or otherwise, do not go astray.

THE PAST YEAR'S WORK.—Messrs. Drake and Gorham, whose speciality is country house lighting, notify us that, notwithstanding the fact of Mr. Drake's serious accident at the New Scotland Yard, and his consequent disablement, they have carried out about 50 installations during the past year, many of which were of considerable magnitude. Amongst these installations may be mentioned the lighting of parts of the Westminster and St. George's Hospitals, and the design and supply of special electrical apparatus for use in connection with surgical operations, and the work for the London County Council at the Weights and Measures Testing Station, Newington. In the Instrument Department, the Cardew voltmeters, the patents for which are held by Messrs. Drake and Gorham, have had a large sale, and the Cardew earthing device has been during the year formally approved and sealed by the Board of Trade. D.P. Batteries have also been received with favour by the trade, &c.

——— The General Electric Power and Traction Company (Limited) has reached the end of its first financial year, and, in spite of the legislative and local obstacles to electric traction, considerable progress has been made. The service of electric cars at Barking has been improved, and, owing to the experience there

Digitized by Google

gained in estimating for maintenance contracts on a large and commercial scale, the Company has reason to expect traction orders to the extent of £150,000 during the coming year. The sub-contract with the Electrical Power Storage Company for the maintenance of the accumulators at a fixed mileage rate removes the only doubt which capitalists may have had for the success of this form of electric traction. At Liverpool, a self-contained car was successfully run for some months with ordinary cars; and a motor car is being built for use in Birmingham. In mining work the Company has fully doubled the quantity of work done in this department in the preceding year; and in launch work, during the busy periods of last season the Company practically controlled the pleasure traffic of the Thames. An electric pinnace of the man-of-war type at the Naval Exhibition, shown equipped ready for slinging in davits, has led to three sea-going boats, 50ft. in length, being despatched to Russia. On Lake Windermere the Company's launches were usefully employed during the whole of the season, and arrangements have been concluded with the Manchester Ship Canal Syndicate by which a fleet of electric launches will run on part of the Ship Canal early in the spring. The Company are about to erect an extensive electric copper refining plant on the banks of the Thames, which they hope to have in full operation about April next.

COMPANIES' MEETINGS & REPORTS.

Mutual Telephone Company (Limited).

A meeting of the shareholders of this Company was held in Manchester on Thursday last, Mr. A. D. Provand, M.P., in the chair, when the following report of the Directors was read :—

The Directors have the pleasure of submitting to the shareholders their first report and statement of accounts, made up to Oct. 31, 1891. The accounts do not represent an ordinary working period, but must be submitted in order to conform to the requirements of the Articles of Association. The capital account shows that from the formation of the Company to Oct. 31, 1891, the sum of £21,539. 2s. 6d. has been expended on the construction of the Company's exchange system in Manchester, and that £1,574. 16s. 8d. has been expended in other places where it is proposed to open exchanges. The revenue account represents only a working period of four months, viz, from July 1 to October 31, 1891, the former being the date from which, with the exception of £191. 15s. previously charged, the Company commenced to earn revenue. This account shows a gross rental of £3,906. 5s., of which £1,145. 1s. is applicable to this period, and £2,761. 4s. has been carried forward to next account, as representing rentals received in advance for periods extending beyond October 31, 1891. The amount at the credit of the account is £378. 11s. 7d., which the Directors propose to carry forward.

The business of the Company is proceeding in a very satisfactory manner. At the date of this report, 840 instruments are in connection with the Company's exchange. This leaves a large number of applicants still to be joined up, while additional applications are being received daily. Attention is also being given to the work of connecting by trunk wires the various manufacturing centres around Manchester, and your Directors hope before long to offer to the subscribers these facilities. Arrangements have been made to open call-boxes on the main boards of the Royal Exchange, and these will shortly be ready for the use of subscribers to the Company's system.

The Directors feel that they may congratulate the shareholders upon the Company having already proved itself an accomplished success, both in respect of the advantage of the metallic circuit (*i.e.*, the double wire), as affording clearness of speech, and as confirming the views held by the promoters of the Company that a telephone service, worked with the most modern improvements, can be supplied at rates much below those hitherto charged.

The retiring Directors are Messrs. Provand and Southern, who, being eligible, offer themselves for re-election. The auditors, Messrs. Thomas Wade, Guthrie, and Co., also retire, and are eligible for re-election.

The report was adopted, great gratification being expressed at the favourable state of affairs disclosed therein; and the retiring directors and auditors having been re-elected, the proceedings, which were merely formal, closed with the usual vote of thanks to the chair.

Eastern Telegraph Company (Limited).

The following is the report and accounts of the Directors for the half-year ended September 30, 1891, to be presented at the thirty-ninth half-yearly ordinary general meeting, to be held at Winchester House, E.C., on Thursday, January 14, at 1 p m. :—

The revenue for the period amounted to £354,939. 5s. 4d., from which are deducted £97,130. 15s. 1d. for the ordinary expenses and £47,047. 18s. 1d. for expenditure relating to repairs and renewals of cables, &c., during the half-year. After providing £4,816. 5s. for income-tax, there remains a balance of £205,944. 7s. 2d., to which is added £313. 15s. 9d. brought from the preceding half-year, making a total available balance of £206,258. 2s. 11d.

From this balance there have been paid—			
Interest on Debentures and Debenture Stock.....	£28,274	12	10
Dividend on Preference Shares	20,474	3	0
Two interim dividends of 2s. 6d. per share each on ordinary shares	100,000	0	0
	£148,748	15	10

Leaving a balance of £57,509. 7s. 1d., which is carried forward to the next account.

The revenue includes £33,398. 18s. 5d., dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies.

The traffic over our whole system is satisfactory, and the revenue derived from Australian telegrams since the reduction of tariff is developing favourably.

In accordance with the provisions of the Articles of Association, two of the Directors, Sir A. J. Leppoc Cappel, K.C.I.E., and Lord Sackville A. fCecil, retire by rotation at this meeting, and, being eligible, offer themselves or re-election. The Auditors, Mr. Henry Dever and Messrs. Welton, Jones, and Co., retire, and offer themselves for re-election.

Direct United States Cable Company (Limited).

The following is the report of the Directors of this Company for the six months ended December 31, 1891, to be presented at the twenty-ninth ordinary general meeting, to be held at Winchester House, E.C., on Friday, January 15, at 2 p.m. :—

The half-year's revenue (subject to revision on settlement of the case mentioned below) after deducting out-payments, amounted to £45,402. 0s. 8d. against £43,346. 13s. 7d. for the corresponding period of 1890, being a difference of £2,055. 7s. 1d. in favour of the half-year under review.

The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cable, amounted to £17,672. 16s. 5d., leaving a balance of £27,729. 4s. 3d. as the net profit, making, with £3,502. 1s. brought forward from the previous half-year, a total of £31,231. 5s. 3d. For the corresponding period of 1890 the working expenses and other payments amounted to £17,555. 12s. 7d.

Interim dividends of 3s. 6d. per share for the quarter ended September 30, 1891 (paid October 24, 1891), and of 3s. 6d. per share for the quarter ended December 31, 1891 (payable January 23, 1892), together amounting to £21.248. 10s. have been declared; and, after setting aside £5,000 to the reserve fund account, the balance of £4,982. 15s. 3d. on the revenue account has been carried forward.

During the period under review an interruption to the main cable, occasioned by a vessel's anchor, occurred near Artimon Bank, and was promptly repaired. The cost of the repair (£4,478. 0s. 10d.) has been charged to the reserve fund account as heretofore.

Permanent station buildings are about to be constructed at Ballinskelligs, co. Kerry, at an estimated cost of about £4,000, to replace the temporary wooden structures erected 17 years ago.

In the case of the Anglo-American Telegraph Company *v.* Cie. Française du Télégraphe de Paris à New York, the hearing by the Court of Appeal on the question of damages is still pending.

NEW COMPANIES, STATUTORY RETURNS, &c.

ST. PAUL'S PRINTING AND PUBLISHING COMPANY (LIMITED).—This Company was registered on Dec. 31, 1891, with a capital of £10,000 in £1 shares, by R. Hewlett, 31, Essex-street, Strand, W.C. Objects: to establish, print, and publish a newspaper or newspapers, trade journals, magazines, and other publications in England; to acquire the whole or any part of the business, property, and liabilities of any person or Company carrying on any business which this Company is authorised to carry on, or possessed of property suitable for the purposes of this Company, including the copyright of any book, magazine, trade journal, newspaper, or other publication, and to carry on the business of newspaper proprietors, printers, publishers, booksellers, &c. The subscribers are :—

	Shares.
Henry Alabaster, 14, Therapia-road, Honor Oak, publisher	1
T. Ernest Gatehouse, 22, Paternoster-row, London, publisher	1
John Hunt, 222, Upper Thames-street, London, paper merchant.....	1
William G. Wicken, 41, Redcar-street, N., compositor	1
William B. Warwick, 1, Saunders terrace, Wellesley-road, Leytonstone, engraver	1
Edgar S. Middleton, 510, Holloway-road, London, N., book-keeper and clerk	1
Jarvis E. Osborn, 8, Wicklow-street, King's Cross, W.C., publisher's clerk	1

The qualification of every Director appointed by the subscribers of the Memorandum of Association, or subsequently, shall be the holding in his own right of shares or stock of the Company of the nominal value of £200. A Director may, however, act before acquiring his qualification. For the rest, the regulations of Table A, set forth in the schedule of the Companies' Acts, 1862, mainly apply.

CENTRAL ELECTRICAL COMPANY (LIMITED).—This Company was registered on December 28, 1891, with a capital of £50,000, divided into 5,000 Preference and 45,000 Ordinary shares, by T. T. Hull, 22, Chancery-lane, W.C. The objects are to adopt and carry into effect an agreement

Digitized by Google

expressed to be made between Knud Sando and the Company to carry on the business of electricians, mechanical engineers, suppliers of electricity for the purposes of light, heat, motive-power, or otherwise, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. Unless otherwise determined by a general meeting, the number of Directors is not to be less than three nor more than seven, the first to be appointed by the subscribers to the Memorandum and Articles of Association. Qualification, £100 ; remuneration, £100 each per annum, and 10 per cent. of the net profits divided between them. Solicitors: Messrs. J. and H. Gregory, Leslie, and Hartley, 15, Union-court, Liverpool.

CHELSEA ELECTRICITY SUPPLY COMPANY (LIMITED).—An agreement made December 29, 1891 (and filed on the following day), made between the above-named Company (referred to as "the Chelsea Company") of the one part, and the Brush Electrical Engineering Company (Limited) (referred to as "The Brush Company") of the other part, states that whereas, by an agreement, dated July 9, 1888, made between the Chelsea Company of the one part, and the Anglo-American Brush Electric Light Corporation (Limited) (referred to as "the contracting Company") of the other part, it was agreed that the contracting Company should supply, deliver, and fix in working order, in such place in Chelsea as the Chelsea Company might direct, certain plant, and that the Chelsea Company should issue to the contracting Company 84 fully paid up Founders' shares in the Chelsea Company, and should also pay £6,488 to the contracting Company ; and whereas the contracting Company have agreed, at the option of the Chelsea Company, to accept payment of all or any part of the contract price in fully paid-up ordinary shares in the Chelsea Company ; and whereas, by another agreement, dated July 31, 1888. made between the Chelsea Company of the one part and the contracting Company of the other part, it was agreed that the contracting Company should supply, deliver, and fix, in such places in Chelsea or Kensington as the Chelsea Company might direct, certain plant, and that the Chelsea Company should pay to the contracting Company the sum of £1,592 ; and whereas, by an agreement dated December 11, 1889, between the Chelsea Company of the one part, and the Brush Company of the other part, it was agreed that the Brush Company should accept payment of the whole of the amount payable under the agreement dated July 31, 1889, in fully-paid ordinary shares or in cash at the option of the Chelsea Company ; and whereas the Brush Company was incorporated for the purpose of acquiring the undertaking of the contracting Company (the said Company having resolved to wind up voluntarily) ; and by an agreement dated September 4, 1889, the contracting Company and its liquidators agreed to transfer and the Brush Company agreed to acquire as a going concern the real and personal property of the contracting Company ; and whereas certain additions to and deductions from the work specified in the agreements dated July 9, 1888, and July 31, 1889, have been agreed upon between the parties to this agreement ; and the Chelsea Company have exercised their option to pay the whole of the balances due under those contracts in ordinary shares of the Chelsea Company, to be issued as fully paid-up shares, and the sum of £3. 2s. 4d. in cash, and it is declared and agreed that the balances due under the last recited agreements are respectively £1,320 and £1,108. 2s. 4d., and 84 founders' shares of the Chelsea Company ; it is therefore hereby agreed that, in consideration of the work done and plant supplied, and in payment of the said sums of £1,320 and £1,108. 2s. 4d., the Chelsea Company shall issue to the Brush Company, 84 Founders' shares in the Chelsea Company, numbered 20,167 to 20,250 inclusive, 485 ordinary shares, numbered 4,532 to 4,856, from 6,854 to 6,891, and from 7,082 to 7,203 inclusive, the said shares to be considered as fully paid-up, and shall pay to the Brush Company the sum of £3. 2s. 4d. in cash. Registered office of the Chelsea Company: 12, Draycott-place, Chelsea, London, S.W.

"ECLIPSE" ELECTRIC LIGHTING SYNDICATE (LIMITED).—The annual return of the above-named Company, made up to December 31, 1891, was filed on January 1, 1892. The Company was registered on February 6, 1888, with a capital of £20,000, in £1 shares, the first Directors being Sir Charles Clifford, Bart., John Garford, Esq., and Valentine Robinson, Esq. By an agreement made February 4, 1888, between John Garford, Esq., of 3, Vernon-chambers, Southampton-row, London, of the one part, and W. H. Power (on behalf of the Company) of the other part, it was agreed that the vendor should sell and the Company should purchase the business of an electrician and mechanical engineer carried on at the White House, Telegraph-street, E.C., by the vendor, and also patents (1) No. 8,228, of July 7, 1885, United Kingdom ; (2) No. 4,744, of March 30, 1887, United Kingdom; (3) No. 21,745, of March 30, 1887 for Italy ; (4), No. 77,647, of May 31, 1887, for Belgium ; (5) No. 183,287, of May 3, 1887, for France ; and (6) 367,294, of July 29, 1887, for the United States of America. The purchase consideration was £15,000, of which £5,000 was to be paid in cash, and the remainder to be fully satisfied by the allotment of 10,000 fully paid up shares in the Company. At the date of making up 15,357 shares had been taken up, upon 4,380 of which the full amount had been called and paid. The remaining 10,777 had been issued as fully paid. The principal shareholders are Sir Charles Clifford, Bart., of 51, Cromwell Houses, South Kensington (1,072 shares) ; John Garford (4,497), B. Harrison, of the Grange, Leamington Spa (3,000) ; and Valentine Robinson, of 11, Poultry, Cheapside, London (1,951). Registered office : 2, Pancras-lane, Queen-street, London, E.C.

ELECTRICAL PURIFICATION ASSOCIATION (LIMITED).—The annual return of the Company, made up to December 30, 1891, was filed on the following day. The Company was registered on June 23, 1889, with a capital of £15,000, in £1 shares, to acquire and develop certain patents, No. 1,333, No. 15,760, No. 15,939, of 1887 ; No. 472, of January 11. 1888 ; and No. 4,105, of January 24, 1888, relating to the treatment of sewage and other impure liquids by electric action. In January, 1890, the capital was raised to £25,000, by the addition of 10,000 new shares of £1 each. At the time of making-up, 17,176 shares had been taken up, on 12,176 of which the full amount had been called, resulting in the payment of £11,659, leaving £517 in arrears. The remaining 5,000 had been issued as fully-paid. The principal shareholders are W. Webster, electrician, of The Grove, Lee, S.E. (2,600 shares) ; E. Webster, of 234, South Norwood-hill, S.E. (5,892) ; and T. Slater, of 19, Great George-street, Westminster, S.W. (2,542). Registered office: 22, Great George-street, Westminster London, S.W.

ISLE OF WIGHT ELECTRIC LIGHTING COMPANY (LIMITED).—The following notice was filed on December 31, 1891 :—At an extraordinary general meeting of the members of the above-named Company, duly convened and holden at the Mansion House-buildings, London, E.C., on Thursday, December 3, 1891, special resolutions to alter the Company's Articles of Association were unanimously passed. And at an extraordinary general meeting of the members, duly convened and holden at the above address, on Friday, December 18, 1891, the same resolutions were unanimously confirmed. One of the resolutions is, "That of the shares mentioned in the Memorandum of Association, 940 shall be called ordinary shares and 60 shall be called Founders' shares." The above-named Company was registered on November 12th last, with a capital of £1,000, in £1 shares. Registered office : 21, Lime street, London, E.C.

WILLIAMSON ELECTRICAL AND ENGINEERING COMPANY (LIMITED).—The following notice was filed on the 28th December, 1891. At an extraordinary general meeting of the above-named Company, duly convened and held at the registered offices, 14, St. Ann's-square, Manchester, on Tuesday, the 24th of November, 1891, special resolutions altering the regulations of the Company were duly passed, and at a subsequent extraordinary general meeting, also duly convened and held at the same place, on Wednesday, the 9th of December, 1891, the said special resolutions were duly confirmed. The annual return of the said Company, made up to the 23rd of December, 1891, was filed on the 31st following. The Company was registered on the 13th of September, 1889, with a capital of £5,000 in £10 shares, to carry on the business of electrical and general engineers in New South Wales. In July, 1891, the capital was raised to £25,000 by the creation of 2,000 new £10 shares. At the time of making-up 250 shares had been taken up, the full amount called and all calls paid. Mr. J. R. H. Williamson of 14, St. Ann's-square, Manchester, and 15, Pitt-street, Sydney, New South Wales, is the principal shareholder, having 43 shares. Registered office: 14, St. Ann's-square, Manchester.

KEIGHLEY ELECTRICAL ENGINEERING COMPANY (LIMITED).—An agreement made the 27th October, 1891, between H. Boardman, electrical engineer, of the first part, Ira Ickringill, of the second part, C. J. Garnett, electrical engineer, of the third part, A. Moore, of the fourth part, C. H. Seed, of the fifth part (called the vendors), and S. Hey (for and on behalf of the above-named Company), of the sixth part, states that whereas H. Boardman and Ira Ickringill are joint owners of Patent No. 7,720, dated 26th May, 1888, for "Improvements in Electric Tell Tales for checking watchmen and for other similar purposes," and Patent No. 3,878 of 1887, for an "Improvement in connection with Electric Alarm Checks," and whereas C. J. Garnett and A. Moore are the owners of the Patent No. 19,531, and dated December 1st, 1890, for "Improvements in means of automatically recording or checking the time of entrance of *employés* into factories, workshops, and the like," and the said C. J. Garnett is also the owner of the business of electrical engineer carried on by him at South Keighley, and whereas the said C. J. Garnett and A. Moore have verbally agreed to sell one-third share or interest in the patent owned by them, and whereas the above named Company was about to be formed with the objects of acquiring, working, and developing the said patents and business, it is therefore agreed that the Vendors shall sell and S. Hey shall purchase on behalf of the Company the patents, business, &c., described above, and in full consideration £3,300 shall be paid to the vendors. Full particulars of this Company were given in *The Electrician* of last week. Registered office (filed the 28th December, 1891): 8, Devonshire-street, Keighley, Yorkshire.

We are asked to state, with reference to a paragraph in our last issue, that the patents belonging to Mr. Joseph Slater Lewis have been taken over by The National Telegraph Works Company, Limited.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The Directors announce that they are prepared to receive applications for the unallotted balance of the Five per Cent. Perpetual Preference Shares. The traffic receipts for the week ended January 3rd amounted to £878, as against £805 for the corresponding period of 1890-91, an increase of £73.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of December were £3,400, as compared with £3,089 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of December, 1891, were £2,180, against £2,130, showing an increase of £50, as compared with the corresponding period of 1890.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of December, 1891, amounted to £55,830, against £55,058 in the corresponding period of 1890.

Digitized by Google

EASTERN EXTENSION TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for December, 1891, amounted to £38,898, as against £43,482 in the corresponding period of last year.

ELECTRIC CONSTRUCTION CORPORATION.—In the January report of Mr. W. W. Duncan, discussing the value of various companies' stock, we find the following:—"In the two years this Company has been in existence it has returned to its shareholders 12 per cent. in the shape of dividends, has put £25,000 to its reserve fund, and has carried forward to next year nearly sufficient to pay a further 4 per cent. dividend. In addition it has written off capital for patent rights sold and amounts received for licenses the large sum of £120,000. It being able to produce such satisfactory results as a new company out of an enterprise which may still be said to be in its infancy, surely justifies the hope, with the strides that electricity is now taking, that we shall have much more brilliant results in the immediate future. This, to my mind, is a certainty, and I know of no better chance for exceptionally profitable investment than these shares afford, obtainable, as they are at present, at 7 for the £10 fully-paid shares cum 12s. dividend."

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company in December, 1891, were £22,400; January 1st to December 31st, £282,600; corresponding months, 1890, £280,000; 1889, £274,800.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for December, 1891, were £2,364, showing a decrease of £252 as compared with the corresponding period.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 713.—Vol. XXVIII. FRIDAY, JANUARY 15, 1892. PRICE SIXPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The proposals with regard to electric and magnetic units brought forward by M. Hospitalier at Frankfort will be found in the present issue. These proposals are neither revolutionary nor visionary; their author is neither anxious to discard the C.-G.-S. system and to begin again *de novo*, nor to do away with that obnoxious 4π and the many other obstacles which at present mar the simplicity of electro-magnetic calculations. Chemists and mathematicians have an international system of symbols and notation, and there is every reason, M. Hospitalier thinks, why electricians should have one also. The idea is not indeed new, though it has not before been so methodically worked out. Those who have the requisite leisure and knowledge of the subject will do well to refrain from the fascinating pursuit of word-coining and to turn their attention to these more practical and useful suggestions, with a view to their further improvement and their authorisation at the next International Electrical Congress. For our own part we fail to see any good reason for using the scrabbly *ronde* letters 𝔓, 𝔈, and 𝔅 respectively, for magnetising force, intensity of magnetisation, and magnetic induction, instead of the bold block letters **H**, **I**, and **B**, which have come into general use both in England and America, and have the added advantages of being easier to write and clearer to print.

A fortnight ago we alluded to the disinclination which is felt by a tenant with a short lease to present his landlord with fixtures in the shape of electric light wires, switches, and fittings. An attempt to meet this difficulty has been made in the formation of a Company for hiring and maintaining electric fittings; but a perusal of the prospectus does not convince us that it touches the real difficulty. The objects of the Company appear to be merely to wire houses and furnish fittings on the hire-purchase system. Not a word is said about the landlord, and "it is proposed that the amount should be spread over five years, in twenty quarterly payments." Few tenants with a three or four years' lease and an uncertainty of renewal care to go to the expense of wiring a house, nor would they even if the payments were spread as conveniently as possible and without interest. Five years, instead of being a maximum, should be considered as a minimum. Consumers will rarely look on the use of wires and switches as part of the expense of electric light, but consider it to be part of the value of the house, like the gas and water pipes.

An eight-candle lamp costs 8s. to 10s. a year for current, and costs from £1. 10s. to £2 to set up. The cost of wiring and fitting a house may therefore be said to approximately equal the cost of four or five years' consumption, or, in other words, to double the cost of electric lighting for the first five years. Assuming that electric lighting, if carefully managed, costs fifty per cent. more than gas, the annual total cost during the five years over which payment for fittings is spread will come to about three times the price of gas. The proposed Company does not thus offer much assistance to a five-year tenant. If he could pay a moderate sum for the use of the wires, just as he pays for the hire of a gas meter, and might leave the whole when he gave up the house, an immense increase of business would accrue to the supply companies. The hire-purchase system, besides encouraging too often disreputable practices on both sides, offers a sad temptation to persons with limited incomes to make a great show. The vendor is generally well protected and is often extortionate. But it does not appear that this new Company can have any rights to the wires, which must become landlord's fixtures. They say, "the business will be a safe one to the Company, as the fittings will remain its property until the expiration of the hiring period, and until all the instalments are duly paid." We assume that by "fittings" is meant brackets, lampholders, &c., which are not essential and are easily replaced.

So hard is it at present to answer the question, "What is electricity?" that many people would say that to attempt it is to waste time. A few weeks ago we discussed the much more elementary problem, "Does electricity exist?" But a discussion has arisen on the harder question; and the last contribution does not throw much more light on the matter. Our correspondent overlooks the fact that in the vast majority of cases the waste of energy in heating the wire is but a small part of the total energy conveyed by the current; so that whether energy is supposed to be carried with the current, or to flow through the dielectric, as the orthodox theory asserts, we must in either case assume that the larger part of the energy is conveyed without having any influence on the molecular structure of the wire. At the beginning of our abstract of Mr. Trouton's lecture on p. 280, our present knowledge of an electric current is clearly stated. The surrounding medium is thrown into a peculiar condition. It is hardly possible that this can be other than a displacement or strain. "Very few," says Dr. Johnson, "have abilities

Digitized by Google

requisite for the discovery of abstruse truth; and o those few some want leisure and some resolution."

THE coloured map which forms the Supplement of the present issue shows the streets in which electric mains were laid down to the beginning of the present month. The same system has been adopted as in the map published last year, for indicating the competition of the different companies; but by means of ruled tints we have been able to show in addition the extent and the overlapping of the different districts. This map is on the scale of 2½ inches to the mile, being smaller than that of last year, in order to take in the mains of the St. Pancras system. We have not included the City, since no general supply was ready at the beginning of the year, although the work of laying the mains is at last being pushed on with alacrity. The distributing mains of the London Electric Supply Corporation on the south of theThames are not given, as they extend to a considerable distance eastwards. The New Cadogan Company only received its order a few months ago, and until then employed overhead wires; it has concurrent powers with the Chelsea Company; it will no doubt have made sufficient progress by next January to be worth recording.

OUR able contemporary, the *Journal of Gas Lighting*, has been led to imagine that the map which is published with the present issue was to be accompanied by some statistical information relating to the working capabilities of the various supply companies. We made no such promise, and hope that the tables which, according to our usual custom, appeared in our New Year's number will suffice for the present. These tables were but slightly modified from those of last year, for the result of asking a number of miscellaneous questions would merely be a few desultory replies and a great many of blanks. It seems uncertain whether the Board of Trade returns of the supply companies are to be published or no. We may be quite sure that some companies will have no hesitation in throwing them open to public inspection, while certain others will probably take advantage of privacy if no official publication is made. The chief point of interest, in our opinion, will not be the details which go to make up the 2d. of "sheer cost" of output, but those which absorb the 4d. to 6d. which is spent on distribution and general expenses. Our valued contemporary, as well as our other readers, shall have all the authentic information that we can obtain on this subject.

Montreal.—The Canadian Pacific Railway Company intend to start a telephone company in Montreal, in opposition to the Bell Company.

Prof. Hertz.—The Royal Academy of Science at Turin has awarded the Brescia premium of £500 to Prof. Hertz for his researches on electricity.

The Birmingham Compressed Air Power Scheme.—An order has been made for the winding-up of the Birmingham Compressed Air Power Company.

Telegraphic Extension in China.—The Chinese Government proposes to establish a telegraph line from Pekin to Kiakhta, in Siberia, where the Muscovite system at present terminates.

Madrid.—The Electric Supply Company of Madrid, an English company, says *Industries*, has lowered the price of electricity to 1s. per kilowatt hour. The present price of gas is 9s. per 1,000 cubic feet.

The Telephone Service in Belgium.—The Belgian Government has informed the Belgian Telephone Companies of its intention to resume from January 1, 1893, the working of all the telephone lines in Belgium.

Eastern Extension Telegraph Company.—The Eastern Extension Telegraph Company notify that their Hong Kong-Bolinao cable is now repaired, and telegrams can, therefore, be accepted for transmission to Manila as usual.

The Chicago Exhibition.—The plans for the electric lighting of the Chicago Exhibition have been completed, and tenders are about to be invited for the installation and working of plant and mains for 7,000 arcs and 120,000 incandescents.

Church Lighting.—The fine old cathedral of St. Nicholas, Galway, was for the first time publicly lighted by electricity on Christmas morning. The lighting is mainly by high-candle-power incandescent lamps, and is very satisfactory.

The Edinburgh Electric Supply Corporation.—We have received from this Company a pamphlet setting out the objects of the Company, the cost of lighting, &c., and giving information and particulars relating to electric light and power.

Professor Ayrton's Presidential Address.—At the meeting of the Institution of Electrical Engineers last evening, it was decided, owing to the death of the Duke of Clarence, to adjourn until the 28th inst., when Prof. Ayrton will deliver his Presidential Address.

Municipal Lighting.—The Wolverhampton and Walsall Town Councils have each decided to devote £21,000 to electric lighting.—The Watch Committee of the Chester Town Council have also decided to spend the sum of £20,000 on the electric lighting of the city.

Proposed Multiphase Central Station.—A central station is shortly to be built in Baden (Switzerland) by the firm of Brown, Boveri, and Co. The multiphase system is to be applied, and the dynamos, which are to be driven by turbines, are only to run at 40 revolutions per minute.

Telegraph Line to Gilgit.—The party sent to survey the telegraph line to Gilgit has, says the *Indian Engineer*, been obliged to return to Srinagar from Astor, owing to the road being impassable from heavy falls of snow. They will most likely remain there till February.

A Telegraph Pioneer.—A memorial tablet has recently been affixed to the house, now called Kelmscott House, Upper-mall, Hammersmith, occupied in 1816 by Mr. Francis Ronalds, afterwards Sir Francis Ronalds, F.R.S., who there constructed his first experimental telegraph line.

Dockyard Lighting.—The electric light has been introduced at Devonport Dockyard for lighting up the ships under construction there. This is the first time that anything of the kind has been attempted at Devonport, although the light has been tried at Chatham and Portsmouth.

Battersea Polytechnic.—A course of ten lectures on "Recent Applications of Electricity" is being delivered under the auspices of the University Extension Society, by Dr. J. W. Waghorn, in the Public Library, Lavender Hill. The first lecture was delivered yesterday evening.

Frankfort-on-Main.—The *Frankfürter Zeitung* announces that the project for building a central station at Frankfort is about to be carried out. Herr Oscar von Miller and Baurath Lindley have been entrusted with the preparation of the plans, and £500 have been voted for the preliminary expenses.

Electrical Utilisation of Water Power.—The Inverness Police Commissioners are inquiring whether the water-power in the neighbourhood of Inverness is capable of being utilised for electrical purposes. It is proposed to adopt a plan by which water could be got from the canal near Muirtown at a cost of £7,200.

St. Petersburg Exhibition.—We learn that the work of completing this Exhibition is progressing satisfactorily. A portable telegraph will be exhibited by Prince Lvoff; metal working by electricity will be shown by M. Slovinoff; and the Thomson-Houston Company are installing a number of motors for drilling and sawing purposes.

Académie des Sciences.—At the meeting of the Académie des Sciences on the 21st ult. the La Caze prize was awarded to M. Violle for his work in connection with solar radiation, the determination of elevated temperatures and standards of light. For 1892 the subject of the Gay prize will be "A Study of Terrestrial Magnetism, and especially of the Distribution of the Magnetic Elements in France."

Thunderstorms.—On Friday last there was a considerable fall of snow on the north-east coast, and early in the evening at Newcastle and at Seaton-Delaval there was thunder and remarkably vivid lightning. About four o'clock on Saturday morning a thunderstorm took place at Hartlepool, which was renewed later in the morning, the lightning doing damage at the works of Messrs. Gray and Co., and injuring a workman.

Southend Pier Tramway.—In our issue of January 1st, under the heading of "Electric Tramways and Railways in the United Kingdom," we gave the length of Southend Pier as $\frac{1}{4}$ mile. It should read $1\frac{1}{4}$ miles. We may also state that, although the tramway was worked by the Local Board, up to the end of last season Messrs. Crompton and Co. contracted to find the labour and superintend the working for a certain sum.

Exhibition of Meteorological Instruments.—The Council of the Royal Meteorological Society have arranged to hold, at 25, Great George-street, from March 15th to 18th, an Exhibition of Instruments, Charts, Maps, and Photographs relating to Climatology. The committee will also be glad to show any new meteorological instruments or apparatus invented or first constructed since last March, as well as photographs and drawings possessing meteorological interest.

The Price of the Kilowatt Hour in Paris.—

Company.	1889.	1890.
Edison	Fr. 1·104	Fr. 1·237
Victor Popp	1·497	1·265
Place Clichy	1·499	1·368
Marcel-Deprez	1·367	1·119
Municipality	,,	1·100

For street arcs the companies' charges amount to 71 centimes per kilowatt hour.

"Electrical Plant," Central Lighting Station Number.—This profusely-illustrated publication describes the leading central stations of this country, together with a few Continental ones, and several private plants. It should be of service to those Town Councillors and vestrymen who journey about the country at the ratepayers' expense to visit engine-rooms and interview managers. A glance at its pages shows that it forms a useful record of modern central station practice.

Steam Electric Lighting Plant in Germany.—It is stated by the *Elektrotechnische Rundschau* that at the beginning of last year there were in Germany 731 stationary engines, giving 38,344 H.P., and 63 portables, giving 1,266 H.P., employed in driving electric lighting machinery. The total output would correspond to about 800,000 8-c.p. lamps. Besides these, 177 stationary engines and 12 portables (total 10,000 H.P.) were running electric machinery for other purposes. 16·07 per cent. of the whole power was being utilised in Berlin.

Telegraph Offices in the United States.—From a recent report of the Postmaster-General of the United States, it appears that in the New England States the average distance from the post office to the nearest telegraph office is four miles. In the Middle States the average distance to the nearest telegraph office is three miles. In the Southern States the average distance to the nearest telegraph office is nine miles. In the Western States the average distance to the nearest telegraph office is seven miles. In the Pacific States the average distance to the nearest telegraph office is 13 miles.

Storage Battery Litigation in the States.—On December 2nd an injunction was issued against the Electrical Accumulator Company, Theodore N. Vail and O. E. Madden, forbidding them to infringe the patents of Chas. F. Brush, March 2, 1886, No. 337,299, and October 17, 1882, No. 266,090, for secondary batteries.—On December 7th, a perpetual injunction was issued in the United States Circuit Court, Trenton, N.J., restraining the Accumulator Company from making storage batteries in infringement of the patents of Chas. F. Brush now owned by the Consolidated Electric Storage Company, the successors of the Julien Electric Company.

Endurance of Incandescent Lamp.—To show the capacity of incandescent lamps to withstand the weather, Mr. W. Claude Johnson writes to us as follows:—"I have maintained one of these lamps for four years in a most exposed position in my garden without any difficulty. The lamp is rigidly fixed at the top of a tubular shaft. . . . A concentric cable passes through a gland at the top of the shaft, where the lamp is fixed in a vertical position. The cable is connected directly to the platinum loops of the lamp, the joint being then neatly wrapped with pure para rubber strip, and over this a layer or two of compounded tape, which encloses a small portion of the glass bulb."

Reading.—The Lighting Committee presented a report at a recent meeting of the Town Council, in which they detailed the terms on which the Messrs. Laing, Wharton and Down Construction Syndicate undertook to light the central business area of the Borough by electricity, under the alternative of a five or a seven years' contract. It is estimated that the expense would be about half as much again as the present cost, and that the light would be about 15 times as great as that now enjoyed. The foregoing cost, however, would allow for the lamps being alight the whole night, whereas the gas lamps are entirely shut off or reduced a considerable part of the night.

Royal Engineers and the Institution of Civil Engineers.—The Institution of Civil Engineers has hitherto only accepted Royal Engineers as Associates. On retirement from the army, and on taking up civil engineering, a Royal Engineer, however, becomes eligible for full membership, but up till a short time ago, says *Engineering*, there had been no instance of any one taking advantage of this rule. But this precedent has at length been created, and Major-General Webber figures as the first ex-officer of the Royal Engineers to be accepted as a full member of the Institution of Civil Engineers. General Webber's application for membership was backed by the following names, amongst others, Sir C. H. Gregory, Sir F. Bramwell, Sir Douglas Fox, Mr. Preece, and Sir B. Baker.

The Electric Supply Mains at Liverpool.—On Monday last, at about one o'clock, a short circuit occurred in one of the service boxes of the Liverpool Electric Supply Company, in Parker-street. The initial cause of the short circuit was, as far as can be ascertained, some water which had leaked into the box connecting the conductors. The heat generated melted the bitumen lining of the box, and brought the conductors into contact with the iron. The lead fuses of the service lines entering the box were melted, and it is assumed that the spark at the point of rupture of these fuses set fire to the bitumen. Flames were observed issuing from the service plate over the box, which were promptly extinguished by a policeman on duty near the spot, who threw a quantity of sand over the service plate.

The Electrical Standardising, Testing and Training Institution.—During the earlier part of 1891 some time had to be spent in fitting up the new premises at Faraday House, Charing Cross-road. The standardising and testing departments have had continuous work since they were opened. A good deal of work has also been done by experimenters who rent the private rooms and borrow the apparatus as they require it. Much has been done in the direction of inspecting and reporting upon private installations, testing meters, &c., in cases where disputes have arisen between householders and their contractors or supply companies. In the training department some 50 names are on the books, and we are informed that the companies and firms in affiliation with the Institution have already drawn upon it for assistant engineers.

Suburban Electric Service.—According to the *Electrical World* of New York, the Illinois Central Railway authorities are contemplating the substitution of electric motors for locomotives on their suburban lines. The Illinois Central Railroad has a location at Chicago, says our contemporary, that is especially favourable to a first-class train service, inasmuch as its tracks lie along the lake shore for half-a-dozen miles without a single street crossing, and are walled in so that it is

Digitized by Google

possible to run at almost any desired speed permitted by the necessity of frequent stops. This somewhat advantageous situation would operate in favour of electric traction both as regards speed and as rendering possible a power station within very easy reach of both coal and water supply. Nevertheless, the heavy traffic and frequent stops necessarily limit the speed and make the economy of such a substitution of motive power somewhat doubtful.

The Chelsea Electricity Supply Company.—At a recent meeting of the Kensington Vestry the Works and Sanitary Committee stated that pursuant to the reference by the Vestry of November 25th the Committee had considered the letters from the Board of Trade forwarding the description of the system proposed to be substituted by the Chelsea Electricity Supply Company, in place of that now in force; and recommended that the Board of Trade be informed that the Vestry saw no objection to the proposed new system being adopted, provided a code of rules and regulations similar to those now in force be imposed by the Board. We are informed that this so-called change of system is merely the addition of some continuous-current transformers at the sub-stations, and some direct-running machines at the Central Station for supplying immediately around that station; on account of this the Board of Trade thought it necessary to draw up a revised description of the system.

Royal Society Grants.—The following are a few of the sums appropriated by the Royal Society from the annual Government grant (£4,000) for the advancement of science. E. H. Griffiths, for apparatus required in a re-determination of the value of Joule's equivalent, £50. H. L. Callendar, for the manufacture of a standard platinum thermometer, and the comparison of the same with an air thermometer at high as well as low temperatures, £80. Prof. J. V. Jones, for a further determination of the ohm by the method of Lorenz, £50. Prof. Rücker, and Prof. Thorpe, towards the expense of a magnetic survey of the United Kingdom, £600. Dr. H. Marshall, for a research on the oxidation of various substances (salts, acids, &c.) by means of electrolysis, £25. W. A. Shenstone, for payment of an assistant in investigating (1) the influence of the silent discharge of electricity on gases, (2) the conditions of the formation of haloid salts, £50. Prof. D. E. Jones, in aid of an investigation on Hertzian vibrations, £35.

Government Control of Telegraphs.—In the discussion on Mr. Rosewater's Paper (see *The Electrician*, December 18th, p. 159) on this subject, which took place recently at the New York Electric Club, Mr. Allen R. Foote made some interesting comparisons between the English and American service. Between 1887 and 1889 the number of telegraph offices in the United States was increased by 20 per cent., against an increase of 8 per cent. in England. In the United States there is one telegraph office to every 2,400 of the population; in England there is one to every 5,500. In England we have one office to every 17·27 square miles; in America they have one to every 171 square miles, the populations per square mile being in the ratio of 100 to 5·6. In the United States a message averages close on 22 words, for which the charge in this country would be 11d., but which costs 1s. 8½d. across the Atlantic. The average mileage of a message in America is, however, 540 miles. The longest possible distance in England is 600 miles. Mr. Allen R. Foote opines that one reason why so many people go to America must be "to enjoy the privilege of telegraphing at the low price charged by our grinding monopoly." It is a pity no comparative statistics were given as to the average time an average message takes to go an average distance in the two countries respectively.

The Receipts and Expenditure of the Paris Exhibition.—The *Economiste Français* publishes a detailed analysis of the receipts and expenditure connected with the Exhibition of 1889, the net financial outcome of the Exhibition being a balance of about £400,000 to the good. The receipts were made up of the money paid for admission, the produce of different concessions and lettings of space, the sale of materials afterwards, the subsidy of the city of Paris, and the amount contributed by the State. The receipts of the 1867 Exhibition were £1,050,000, while those for the Exhibition of 1878 did not amount to more than £927,000, including a subsidy of £248,000 from the city of Paris. Upon the other hand, the expenses of the 1889 Exhibition, which had been estimated at £1,860,000, did not amount to more than £1,600,000, while for the 1867 Exhibition they were £936,800, and for that of 1878, £2,216,000, including a sum of £560,000 spent upon the Palace of the Trocadéro. In other words, while the 1889 Exhibition left a profit of £400,000, that of 1867 gave one of only £112,000; and that of 1878, organised at the cost of the State, left a deficit of £1,268,000. It should be pointed out, however, that in 1878 there was no subsidy from the State, whereas in 1889 the State contributed £680,000, and in 1867 £240,000.

Electric Lighting and Heating in the Highlands.—In its issue of January 9th the *Field* gives some particulars with regard to an interesting little application of water-power to electric lighting and heating purposes at a shooting-lodge in the West Highlands. A dam was built across a small mountain burn some 800ft. above the lodge. The water is led for some distance past the dam in an open drain, and at a point about 650ft. above the turbine; it is conducted to it in a closed pipe. The waterfall thus made is the highest that is used for electric lighting purposes in the British Isles. The current is conveyed from the turbine house to the various buildings, the lodge about 200 yards distant, the stables, laundry, and head stalker's cottage some 400 yards distant, by means of insulated conductors laid underground in tarred wood troughing, and the cables are completely protected by melted bitumen run into the troughs. In all, there are some 292 electric lamps installed. An interesting feature of the installation is a system of electric stoves, which are used for warming and keeping dry the cellars and various other parts of the buildings. The whole of the electrical installation was designed and carried out by Mr. J. C. Howell, of Queen Victoria-street, the turbine and water arrangements being carried out by Messrs. Carrick and Ritchie, of Edinburgh.

Artificial Production of Rain.—At the close of a Paper read before the Electrical Section of the Franklin Institute, Prof. Edwin Houston said that the following general conclusions may, in view of the present state of meteorological science, be properly drawn concerning the artificial production of rain:—1. That rain can never be made to fall at will by mid-air explosions on any part of the earth's surface irrespective of the climatic conditions there existing. 2. That during certain meteorological conditions mid-air explosions may result in rainfall over extended areas. 3. That the liberation of energy necessary for such rainfalls is due not to the mid-air explosions, but to the energy stored up in the moist air from which the rain is derived. 4. That the meteorological conditions which must exist for the successful action of mid-air explosions would probably, in most though not in all cases, themselves result in a natural production of rain. 5. That a comparatively high difference of electric potential between different parts of the air, or between the air and the earth, is possibly favourable when taken in connection with other meteorological conditions for artificial rain-making. 6. That an undirected mid-air explosion is not as likely to produce rain as an explosion in which the main tendency of the energy liberated is to cause a general up-rush of the air.

An Incident in a New York Telegraph Office.—Last month at a very busy moment in the New York office of the Western Union, the Baltimore quadruple suddenly broke down. A New York daily describes the incident as follows:—"Wire Chief Durivan was called to adjust the instruments. He pottered over them for some time, and concluded that there was a bug on the wire somewhere between New York and Baltimore. The telegrapher's definition of "bug" is "trouble." The instruments were taken off the wire and the wire was tested. It was found to work splendidly. When the instruments were replaced, however, the wire would not work at all. There were no other instruments available, and the connection with Baltimore was completely lost. Electricians were sent for, and they began a thorough examination of the instruments. After half an hour's search they found the bug, not on the wire,

Digitized by Google

but on the instruments. It proved to be a Croton bug. It stood on the instrument which regulated the passage of the electric current from the dynamo to the wire in such a way as to connect with its fore and hind legs the positive and the negative currents. The bug was dead, of course, and the current of 250 volts had fairly glued it to the metal, thereby forming a conductor interrupting business between New York and Baltimore for more than half an hour."

Electric Heaters.—In the States a large number of electrical heaters have been proposed. As showing their economic inefficiency, they are compared with the cost of gas used in gas stoves for domestic and other purposes. In the paper by Mr. George H. Christian, published in *Engineering News* of May 30 the fuel gas, at 50 cents per 1,000ft. was stated to furnish a given amount of heat at the same cost as hard coal at 7·50 dols. per ton. But with the exception of the natural gas regions there are few cities where gas for heating purposes can be had at this rate. A common price, however, is 1 dol. per 1,000ft., and at this price it is generally considered a very expensive fuel, even for cooking purposes. The total calorific value per 1,000ft. of gas may be taken as 400,000 heat units. The prices of electricity in New York City vary from 14 cents per horse-power hour for incandescent lighting to from 5 cents to 10 cents or more per hour for power purposes. One horse-power, 33,000 foot-pounds per minute, 1,980,000 foot-pounds per hour, equals 2,565 heat units. If 2,565 heat units obtained from electric energy cost 5 cents, for a dollar we can obtain 20 times as much, or 51,300 heat units, assuming no losses. But a dollar's worth of gas will furnish 400,000 heat units; hence the electric heating is nearly eight times as expensive as the heating by gas at 1 dol. per thousand feet.

Portsmouth.—At its meeting last week, the Town Council discussed Prof. William Garnett's proposals with regard to the electric lighting of the town. Prof. Garnett's scheme involves the use of alternating currents at 2,000 volts pressure, turbo-electric generators, and concentric mains. For public lighting Prof. Garnett recommends 150 c.p. incandescents placed 90 feet apart. The capital expenditure for an 18,000-light central station, supplying also 200 public lamps, is estimated at about £38,000, exclusive of cost of site. The annual revenue is figured out at £10,800, and the total expenditure at £7,572. From the discussion on the Electric Lighting Committee's report, it seems that the revenue is based upon every 8-c.p. lamp wired earning 10s. per annum. In presenting the scheme summarised above, the Electric Lighting Committee reported that they had had reason to reconsider the scheme prepared by Mr. Shoolbred, and they had obtained a further report upon the subject from Prof. Garnett, which they now submitted for the consideration of the Council. The Committee recommended that the resolution of the Council passed on September 8th last, so far as it referred to the adoption of Mr. Shoolbred's scheme, be rescinded. They further recommended that the scheme and report of Prof. Garnett be adopted, and that he be appointed as consulting engineer, and that Messrs. Waller and Maneville be appointed as superintendent engineers. An amendment was moved, deferring the consideration of the report for a fortnight, and was carried by 16 to 12.

Western Union Telegraph Company.—The following statistics appeared in a recent issue of *Engineering*. (We have taken the liberty of converting our contemporary's dollars into pounds sterling.) The revenue of this great undertaking for the financial year ending June 30, 1891, was £4,606,865, as compared with £4,477,405 in 1889-90. In 1879-80 the revenue did not exceed £2,556,578, and in 1869-70 it only amounted to £1,427,747. The profits realised in 1890-1 were £1,321,117, as compared with £1,462,545 in 1889-90. In 1879-80 the profits did not exceed £1,166,787, and in 1869-70 they only amounted to £445,421. The enormous expansion of the Company's business is shown in the fact that the number of telegrams despatched by it last year was 59,148,343, as compared with 55,878,762 in 1889-90, 29,215,500 in 1879-80, and 9,157,646 in 1869-70. In 1890-1 the Company had 20,098 offices in operation; the corresponding number in 1889-90 was 19,382; in 1879-80, 9,077; and in 1869-70, 3,972. In 1890-1 the Company had stretched 715,591 miles of wire. In 1889-90 the corresponding length of wire was 678,997 miles; in 1879-80, 233,534 miles; and in 1869-70, 112,191 miles. The Company has been compelled by the force of circumstances to pursue a policy of progressive enterprise, and also to absorb all competitive undertakings as much as possible; hence the prodigious growth of its system and business. The Company was chartered in April, 1856, with a capital stock of £100,000. In July, 1869, this capital had been carried to £8,210,620, and in January, 1881, it had further grown to £16,000,000. At the present time it amounts to £17,239,970. The Company has also now a bonded debt of £3,877,706.

Telegraphic Communication with Lighthouses and Lightships.—In our issue of January 1st we printed some extracts from a letter on this subject which had been sent to *The Times*, by Mr. R. S. Culley. The following is extracted from a letter of Mr. E. Stallibrass, which appeared in Tuesday's *Times*:—"I have no hesitation in saying that, should money be forthcoming for the most important work of establishing communication with our isolated rock lighthouses, there will be no lack of engineers competent to successfully utilise it. It must be apparent to everyone that the difficulties are in no way comparable with those which were successfully overcome by Winstanley, Rudyerd, Walker, Stephenson, Douglas, and others by the construction of the very lighthouses with which it has become so important to establish telegraph communication. There has been, up to now, but one single attempt made, which resulted in failure. Are we to assume from this that the thing is impracticable? It is unreasonable to expect an ordinary type of submarine cable, laid in the usual way, to last under the necessary very unfavourable conditions. The question is not one of weight of the cable, as Mr. Culley thinks, but of specific gravity. Besides employing a type which will offer little resistance to the waves, in proportion to its weight in water, special means must be taken to secure the cable to the rocks. It would be advisable to lay down three or four specially-designed cables on the most sheltered sides of the rock, securing each one separately, but bringing their ends together and joining them to one main cable of ordinary construction at the first favourable spot clear of rocks. It is very unlikely that all these cables would be broken together, and so long as one lasted communication could be kept up."

The Municipal Station at the Halles.—Municipal electric lighting enterprise meets with but scant support in Paris, and if the following statistics, which recently appeared in the *Bulletin International de l'Electricité*, are to be relied on, the reason is not far to seek. The municipal station at the Halles Centrales has a plant capacity of 3,840 kilowatts, 1,075 kilowatts, or 36 per cent., being devoted to public lighting purposes. The financial outgoings and incomings for the first six months of 1891 were as follows:—Expenses: Wages, £1,837; coal and coke (881 and 1,268 tons respectively), £3,284; oil and grease, &c., £437; repairs, £594; total, £6,152. Doubling this we get £12,304 for the year, say £12,600 in round figures. The sales of current come out as shown below:—

Low-pressure system.	Kilowatt hours.		£
Halles Centralles	213,160	.....	6,054
Customers	24,725	.....	1,483
High-pressure system.			
Customers	17,067	.....	1,024
Belle Jardinière	81,583	.....	1,600
Totals	336,535	.....	10,161

Doubling these figures we have totals for the year of 673,070 kilowatt hours and £20,322. In the last municipal budget, however, the accounts showed an apparent profit of £10,216. In the receipts the municipal electricity is charged for at the rate of 1fr. per kilowatt-hour, although the companies only charge the city 71 centimes, so that the receipts are unduly swollen. On the other hand, to station expenses must be added, rent, interest, sinking fund, &c., and these bring up the total outgoings to £19,103. The capital expenditure is £45,200. The cost of production of the kilowatt-hour is 48 centimes, and the total cost comes out at 80·5 centimes, yet current is supplied by contract to La Belle Jardinière for £3,200, which corresponds to 49 centimes per kilowatt-hour, or an annual loss of £2,020.

Digitized by Google

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 251.*)

§ 50. **The Electrodynamometer.**—This instrument, in one or other of its forms, has been of so great assistance in the progress of electromagnetic science that it clearly demands a place in any description of apparatus for the measurement of currents. We shall, therefore, give a brief account of the principles on which the instrument works, and will deal first with the simplest possible case.

Take a large coil of radius A cm. and suspend at its centre a small coil of radius a cm. by a bifilar suspension, the planes of both coils being vertical (Fig. 44). The two wires of the suspension serve also to convey the current to and from the suspended coil. Let a current i flow round both coils. Let the normal position of the suspended coil (*i.e.*, when no current passes) be that in which its plane is at right angles to that of the fixed coil. The fixed coil is placed with its plane in the magnetic meridian. Let ϕ be the angle through which at any time the plane of the suspended coil has turned from its original position. The motion is, of course, in azimuth, *i.e.*, about a vertical axis.

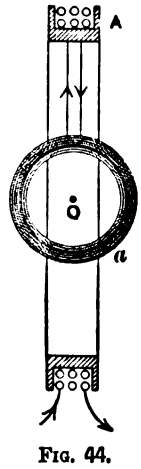

FIG. 44.

Let G be the "galvanometer constant" of the large coil; G is the magnetic force at the centre of the coil when the current in it is unit current. Let g be the sum of the areas of all the windings upon the small coil. Now when a current of strength i flows round the small coil, we can replace each turn of wire by a uniform magnetic shell of "strength" i, as was proved in § 23. Hence the total magnetic moment is $g\,i$. Now we suppose that A is so large compared with a that we may regard the magnetic field produced by a current i in A as sensibly uniform throughout the sphere, of which the circle a is a meridian, and accordingly the same as at the centre of A. The magnetic force at the centre of A is $G\,i$, so that by § 6, when the suspended coil has been turned round through an angle ϕ, the couple due to the large coil which is experienced by the small one is $i^2\,G\,g\cos\phi$ ergs, since the angle between the magnetic axis and the magnetic force is $\pi/2-\phi$. The direction in which this couple tends to turn the coil depends upon the direction of the currents in the two coils, and can be easily understood by referring to §§ 6, 22. The unit couple is such that its moment is equal to the moment of a force of one dyne, about a point, which is one centimetre distant from the line of action of the force. Since the "product" of a centimetre and a dyne is an erg, we may appropriately measure couples in terms of ergs.

Besides the couple due to the large coil, the suspended coil experiences a couple due to the action of the earth. The moment of this couple is $g\,i\,\mathsf{H}\sin\phi$, where H is the strength of the earth's horizontal magnetic field. The action of the bifilar suspension provides a restoring couple of moment $\mu\sin\phi$ ergs, where μ is a constant depending upon the length of the suspending wires, their distance apart and the mass of the suspended coil. Thus, when the suspended coil is in equilibrium under the action of these three couples, we must have

$$i^2\,G\,g\cos\phi = i\,g\,\mathsf{H}\sin\phi + \mu\sin\phi,$$

whence $$\tan\phi = i^2\,G\,g/(i\,g\,\mathsf{H}+\mu).$$

Now the instrument is always arranged and used, so that $i\,g\,\mathsf{H}$ is small compared with μ, so that on expanding this expression by the binomial theorem as far as the second term we find

$$\tan\phi = \frac{i^2\,G\,g}{\mu}\left(1+\frac{i\,\mathsf{H}\,g}{\mu}\right)^{-1} = \frac{i^2\,G\,g}{\mu} - \frac{i^3\,\mathsf{H}\,G\,g^2}{\mu^2}.$$

Let us denote this value of ϕ by ϕ_1. Now reverse the current in both coils, we shall obtain a value of ϕ of the same sign as before, but slightly different in value, thus

$$\tan\phi_2 = i^2\,G\,g/\mu + i^3\,\mathsf{H}\,G\,g^2/\mu^2.$$

Hence by addition we find $\tan\phi_1+\tan\phi_2 = 2\,i^2\,G\,g/\mu$, or

$$i^2 = (\tan\phi_1+\tan\phi_2)\,\mu/2\,G\,g.$$

If we had taken two other readings by reversing the current in first one and then the other of the two fixed coils we should have got two nearly equal values of ϕ, viz., ϕ_3 and ϕ_4, of the opposite sign to ϕ_1 and ϕ_2. Combining these with ϕ_1 and ϕ_2 we should eliminate any error which would arise from the imperfect perpendicularity of the two coils when no current flows through the instrument. Hence we have finally

$$i^2 = (\tan\phi_1+\tan\phi_2-\tan\phi_3-\tan\phi_4)\,\mu/4\,G\,g.$$

The values of ϕ are found in the usual way by attaching a mirror to the suspended coil and observing its deflection by means of a lamp and scale. If x is the deflection, and d the distance of the scale from the mirror, then $\tan\phi = x/2\,d$ approximately.

We must now consider how μ can be found. It is clear that the couple produced by a bifilar suspension is proportional to the mass, M, of the suspended coil. We may, therefore, write $\mu = \lambda\,M$. If T be the time of a complete vibration of the coil about a vertical axis, and K its moment of inertia, we have $T = 2\pi\sqrt{\frac{K}{\lambda M}}$. Now, fix to the suspended coil a bar whose moment of inertia, K′, can be accurately determined, and whose mass, M′, is known, and again observe the time of vibration. We have $T' = 2\pi\sqrt{\frac{K+K'}{\lambda(M+M')}}$. From these two equations we can find $\mu = \frac{4\pi^2\,K'\,M}{M(T'^2-T^2)+M'\,T'^2}$.

The only other quantities we have to determine are G and g Their values in the cases in which the two coils consist of a few turns of wire very close together are easily found. By § 28 we have $G = \frac{2\pi n}{A}$, where n is the number of turns on the large coil of radius A. To find g we remember that it is the sum of the areas of the windings of the small coil. Thus $g = \pi\,n'\,a^2$, n' being the number of turns, and a the mean radius.

§ 51. **Helmholtz's Arrangement.**—An essential point in the theory sketched out above is that the magnetic force at the centre of the small coil due to a current in the large coil should be very uniform. To gain this uniformity, the large coil is made in two halves, and placed with its two halves one on each side of the centre of the small coil. Let A be as before the radius of the coil, 2 B the distance between the two central planes of the two halves (Fig. 45). The problem before us is to find what value of B will make the magnetic force at O most nearly uniform. Let F_1 be the magnetic force due to one coil at a point P, whose distance from that coil is $B+x$, where x is small; then by Taylor's theorem

$$F_1 = F_0 + x\left(\frac{dF}{dx}\right)_0 + \frac{x^2}{1.2}\left(\frac{d^2F}{dx^2}\right)_0 + \ \ldots$$

where the suffixes indicate that in this equation we are to take the values of the quantities when $x=0$. Of course, x is put equal to zero *after* differentiation. If F_2 is the magnetic force

Digitized by Google

due to the other coil when the current flows in the *same* direction as in the first coil, we have since the distance of P from the second coil is $B - x$.

$$F_2 = F_0 - x\left(\frac{dF}{dx}\right)_0 + \frac{x^2}{1.2}\left(\frac{d^2F}{dx^2}\right)_0 - \quad . \quad . \quad . \quad .$$

Thus for the whole magnetic force we have

$$F_1 + F_2 = 2\left\{F_0 + \frac{x^2}{1.2}\left(\frac{d^2F}{dx^2}\right)_0 + \frac{x^4}{1.2.3.4}\left(\frac{d^4F}{dx^4}\right)_0 + \quad . \quad .\right\}.$$

In order that $F_1 + F_2$ may be as nearly as possible independent of x we must have $\left(\frac{d^2F}{dx^2}\right)_0 = 0$. By referring to § 26, we find that $F = 2\pi A^2/\{A^2 + (B+x)^2\}^{\frac{3}{2}}$, so that

$$\frac{d^2F}{dx^2} = -\frac{6\pi A^2\{A^2 - 4(B+x)^2\}}{\{A^2 + (B+x)^2\}^{\frac{7}{2}}}.$$

Thus $\left(\frac{d^2F}{dx^2}\right)_0$ vanishes when $A^2 = 4B^2$, *i.e.*, when $B = A/2$, or the distance between the two coils is equal to their radius. This is called the Helmholtz arrangement. It is often made use of in the construction of tangent galvanometers, as it enables a larger magnet to be used than would be possible with a single central coil without serious error.

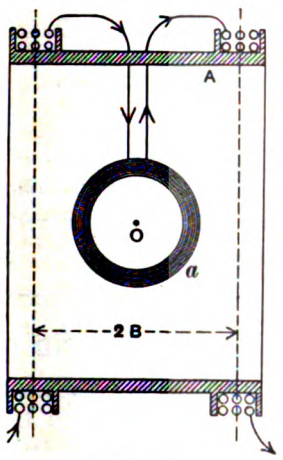

FIG. 45.

Now, the galvanometer constant G of the pair of coils is the value of the magnetic force at the centre of the system for unit current. If these are n turns on *each* of the large coils, we have $G = 4\pi n A^2/(A^2 + B^2)^{\frac{3}{2}}$. In the Helmholtz arrangement B is as nearly as possible equal to A/2, so that in this case we have nearly $G = 32\pi n/5\sqrt{5}\,A$. The diagram of lines of force for the Helmholtz arrangement given in Maxwell, Vol. II. (Fig. 19), shows how perfect is the uniformity of the magnetic field near the centre of the coil. A small correction must be applied to the above expression for G on account of the finite space occupied by the windings.

It is to be carefully noticed that B appears in the value of G, and that when B is nearly equal to A/2, the value of G is very much dependent upon that of B. In the case of the current-weigher, the value of the attraction was nearly independent of B when B = A/2.

The symbol g stands for the sum of the areas of the windings of the small coil. If a be the mean radius, *i.e.*, the radius from the axis to the centre of gravity of the windings, it can be easily found that

$$g = n'\pi a^2\{1 + h^2/12\,a^2\},$$

where n' is the number of turns and h the radial depth of the windings, supposed to be in a rectangular groove. Now it is impossible to determine a by measurement with any accuracy if there are many windings and the coil is small. A better method of procedure is to determine the ratio a/A by a method of comparison such as that of § 29, and to determine A by measurement of the large coil.

Neglecting for the present the small correcting terms, the complete expression for i^2, in terms of the quantities actually observed, is as follows :—

$$i^2 = \frac{x\,K'\,M'(A^2 + B^2)^{\frac{3}{2}}}{2\,d\,\{M\,(T'^2 - T^2) + M'\,T'^2\}\,n\,n'\,A^2\,a^2}.$$

The very appearance of this formula is enough to show that the electro-dynamometer as an instrument for accurate "absolute" measurements labours under many difficulties. Remembering that $K' = M'\,k'^2$, where k' is determined from the shape and size of the inertia bar, we see that the formula can be written

$$i^2 = \frac{\frac{x}{d}\left(1 + \frac{B^2}{A^2}\right)^{\frac{3}{2}}\cdot\frac{k'^2}{A^2}}{2\,n\,n'\left\{\left(\frac{T'^2}{T^2} - 1\right) + \frac{M'}{M}\cdot\frac{T'^2}{T^2}\right\}\frac{a^2}{A^2}}\cdot\frac{M'\,A.}{T^2}$$

The quantities we have to determine are—
the four ratios of lengths x/d, B/A, k'/A, a/A,
the ratio of the two masses M/M',
the ratio of the two times T'/T,
the two numbers n and n'*,

as well as the three quantities M', A and T. The quantities which appear in the form of ratios may be determined in terms of any convenient units, but M', A and T *must* be measured in Grammes, Centimetres, and Seconds. Since the square of a current is on the electro-magnetic system of the same dimensions as a force, it follows that in any determination with an instrument which measures the square of a current, we must of necessity determine in "absolute" C.-G. S. measure a Mass, a Length, and a Time. The best instrument will be that in which these three fundamental quantities are most easily determined with great accuracy.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, January 15th.

JUNIOR ENGINEERING SOCIETY.

8 p.m. Ordinary Meeting. Paper to be read: "Modern Applications of Electricity to Metallurgy." By George C. V. Holmes, Sec. I.N.A.

SATURDAY, January 16th.

ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING.

11 a.m. General Meeting at University College, London. Reports to be presented. Election of Officers.

2 p.m. Papers to be read: (1) "On Laguerre's Dictum concerning Direction." By Prof. R. W. Genese, M.A. (2) "On the Geometrical Interpretation of Fallacy in Elimination." By Prof. R. W. Genese, M.A. (3) "On the use of Horner's Method in Schools." By E. M. Langley, M.A.

TUESDAY, January 19th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "On Weighing Machines." By Wilfrid Airy, B.A., M.Inst.C.E.

WEDNESDAY, January 20th.

ELECTRICAL EXHIBITIONS AND COMPETITION.

It may be confidently predicted that the Electrical Exhibition which was opened at the Crystal Palace on Saturday last will be a success. The first Electrical Exhibition in this country was held in the same building in 1882, and contributed in a very important degree to the progress of electrical engineering. The Paris Exhibition of 1881 was thoroughly international—no one could foresee its scope, and all who visited it were amazed at the already ripe condition of the industry. Electrical engineering was in a most critical condition; the air was full of new inventions, and the public were almost as eager as the scientific world to witness the beginning of a new art, and, we may say, a new feature of civilisation. The first Crystal Palace Exhibition was to a certain extent a *rechauffée* of the one at Paris. The Brockie arc lamps, worthy predecessors of the Brockie-Pell, the Lane-Fox, Maxim, and other glow-lamps, were highly appreciated by the public; the dynamos ran well and inspired confidence among engineers. The succeding Exhibition, in which an attempt was made to pit electricity against gas, though perhaps not so important as a landmark in the history of the subject, enabled many new dynamos and systems to be shown, but failed to establish any real rivalry, and at the present day, though we may compare prices and results, and while we believe that electric lighting will push its way as surely and as extensively as railway locomotion has done, it need not be said to rival or compete with gas any more than railways have competed with horses.

Competition in any industry is a good tonic, but a bad food. When competition becomes an incentive to production, energies and money must be fruitlessly wasted in the struggle. The dynamo practically created its own market; and the Paris and

Crystal Palace Exhibitions were the means by which this was effected. When it was shown what could be done, demand was naturally and healthily followed by supply; but, while competition has braced and invigorated the young trade, and has promoted the refinement and the development of high efficiency, it has at the same time left its mark upon the commercial side of the business. The stigma of rotten-company promotion was being branded on the industry even at the time of the first Crystal Palace Exhibition, and the very life-blood, viz., manufacturing profits, was soon affected; and it is to cut-throat competition that the inadequate return on electrical manufacture is solely due. We hear nothing now of the old cry that electric lighting will become popular when dynamos can be cheapened. Mechanical engineers and engine makers have had time to look into this question, and have been amazed that any one could make a business out of it. The evil side of competition is to be found in the office, and culminates in the enticing price list and the underbidding tender: the good side of competition ought be realised at an Exhibition, and should result in well-arranged tests. A committee of experts has been nominated for the Crystal Palace Exhibition, and we are determined not to be disappointed, for we expect no more from them than from similar committees in bygone Exhibitions—that is, nothing.

An Exhibition such as that which is now open, and which will be fairly complete in a week or two, is promoted with two entirely distinct objects; and, whether or no it achieves these, produces two other distinct results. The proprietors of the Crystal Palace want an entertainment which will draw, while exhibitors hope to increase their business. These objects have practically nothing in common, for the management imposes no commission on sales, as at picture galleries. The Crystal Palace Company may or may not, but probably will be, well rewarded by the shillings of the public, and other sources of profit; the exhibitors will surely book some orders, and might, if nobody else came near them, do good business among themselves. But, apart from these considerations, the public cannot fail to familiarise themselves with the possibilities of electric light and power, and the means by which these ends are attained; and the scientific and engineering world will not miss the opportunity of examining and comparing the *chefs d'œuvres* of dynamo and engine builders, and the countless objects with which the stands and show cases are filled. Our interest in the Exhibition is entirely confined to the last. If a dynamo has been described in our columns we have done with it, but the interest which the public may take in it is not diminished thereby. We intend to confine ourselves to the actual novelties and recent improvements which are to be found, and we have already found several that are well worth presenting to our readers. The old custom of filling columns at this time of the year with records of the past twelve months' work was bad enough; but to print all the descriptions which have been sent to us of exhibits which are perfectly well known to most of our readers would be worse.

Although electric lighting has been a prominent feature of many of the London Exhibitions of recent years, and while the engine-room never fails to attract sightseers, no extensive demonstration of the practical details has been offered for some time; and the public are sure to take this opportunity of investigating them, since most exhibitors provide attendants who can intelligently answer ordinary questions. An amusing change comes over the young man in charge during the progress of an Exhibition. During the first few days he will dart at any one who stops for a moment to look at his stand, or will even "buttonhole" a negligent passer-by. He will reel off a voluble account of the wonders of his wares, and descant on their capabilities. He will be staggered only for an instant if you ask him if he has anything new to show. By the end of the first week his spontaneous spoutings are spent, and he reserves his energies for inquirers. A month later his energies, too, have given out, and in reply to a polite inquiry, "What is a transformer?" he hands a circular, and no one but a possible customer can penetrate his taciturn abstraction. The remainder of the time till the close of the Exhibition is chiefly spent at lunch. If the competition between attendants could be maintained, each vieing with the other to offer intelligent explanations, the public could not fail to be greatly benefited. The technical visitors are interested almost exclusively in recent developments, new inventions, and the latest improvements. An engineer will take more interest in a brush-holder spring or the suspension of a galvanometer than in a row of half-a-dozen dynamos, which have been illustrated in price lists and advertisements for years past. It would be an excellent thing if on certain days the exhibitors themselves could attend, as many did on Friday last. Demonstrations and experiments on such occasions would be greatly appreciated, and the trouble would not be thrown away. Competition in such matters is eminently useful. No sooner do Messrs. Siemens Bros. arrange a 50,000-volt experiment, than Messrs. Swinburne and Co. propose a 100,000-volt set. But this sort of thing can be done all the more thoroughly the longer the interval between successive Exhibitions. An inverted Septennial, or better still Decennial, Act, forbidding the holding of Electrical Exhibitions under pain of attainder, except at stated periods, would be an all-round blessing.

ELECTROTECHNICAL NOTATIONS, ABBREVIATIONS, AND SYMBOLS.*

BY E. HOSPITALIER.

The question of the unification of electrotechnical notations, abbreviations, and symbols, is not absolutely new. In 1885 I brought it before the Société Internationale des Électriciens, and about the same date Prof. Andrew Jamieson did likewise at the Society of Telegraph Engineers. Reform is rendered all the more urgent by reason of the giant strides with which electrical applications have progressed within the last decade; it is difficult to follow them, especially in the case of communications from foreign countries. Is it possible at the present moment to obtain results useful to engineers and electrotechnical men, to create for them a sort of international symbolism, and a uniform, concrete, impersonal notation easily accessible to all? In a part, at least, of the domain of science and of the engineering art this symbolism already exists, and renders the greatest services; algebra, trigonometry, and the calculus have at the present day uniform symbols and notations, which are almost international, and are understood everywhere and by everyone. What has been done for the mathematical sciences can, in my opinion, be equally well done in the case of the physical sciences, provided we go to work methodically and resolutely.

The first and most indispensable point is to establish a clear and precise distinction between a *physical quantity*, its *magnitude*, and the *unit* which serves as a common measure in a given system to all magnitudes of the same kind. A physical formula always establishes a relation between physical *quantities*, each physical quantity being represented by a special *symbol*. The *magnitude* of a physical quantity is represented by the ratio between a physical quantity and the physical quantity of the same kind which is taken as unity. The magnitudes of physical quantities are, therefore, essentially abstract numbers. Finally, the *unit* is a physical quantity of a particular size, which serves as a common measure, multiple, or sub-multiple, to quantities of the same kind; which is designated by a special name, and which allows of abbreviations

* Abstract of a Paper read before the International Congress of Electricians, Frankfort, September 10, 1891.

The C.-G.-S. magnetic and electro-magnetic units have not as yet received special names. They are designated by following the formula with the phrase C.-G.S. units.

No abbreviations.

(*) The International Bureau of Weights and Measures draws an important distinction in time notation, according as it is a question of fixing the *epoch* or the *duration* of a phenomenon. In the former case *superiors* are used, in the second the notation ranges. Example : The experiment began at $2^{h.}\,15^{m.}\,46^{s.}$, and lasted 2h. 15m. 46s., terminating at $4^{h.}\,31^{m.}\,36^{s.}$ I propose to follow this.

(†) The distinction between the different angular units (radians, degrees, minutes, seconds, grades, &c.), and their notations should be studied by a Geodesic Congress. I have no suggestion to offer.

(‡) Abbreviations to be made.

(§) *N* is the number of turns, *L* the length of the solenoid producing the magnetising force.

Digitized by Google

intended to simplify speech or writing. The symbols of physical *quantities* enter into physical formulæ, but *units* never do. Thus, in the C.-G.-S. system, for example, the three fundamental quantities are length, mass, and time, their respective symbols being L, M, T; and the corresponding units are the centimetre, gramme, and second, abbreviated into cm., g, and s. If we take the derived units into consideration, we shall establish by successive definitions the equations connecting the symbols of these quantities and the relations between the units which serve as common measure to each of these magnitudes.

Let us take some examples. *Surface*, a derived geometrical quantity, the product of two lengths, denoted by the symbol S, will have the following equation of definition :—

$$S = L \times L = L^2 ;$$

the unit being the square centimetre represented by the abbreviation cm^2.

Volume, a derived geometrical quantity, the product of three lengths, denoted by the symbol V, will have as equation of definition—

$$V = L \times L \times L = L^3 ;$$

the unit being the cubic centimetre represented by the abbreviation cm^3.

Velocity, a derived mechanical unit, the quotient of a length by a time, denoted by the symbol v, will have the following equation of definition :—

$$v = \frac{L}{T} = LT^{-1} ;$$

the unit being the centimetre per second.

There is, therefore, some reason for observing an essential and definite distinction in the notation and writing of formulæ between the symbols representing physical quantities, and the units which serve as common measure to their magnitudes. With this object in view, italic, Greek and *ronde* type, &c., might be exclusively reserved for *symbols*, and Roman type for *units* and their abbreviations. A single symbol, always the same, might be allotted to each geometrical, physical or mechanical quantity, together with a special name to each corresponding unit. We should thus avoid the confusion of language, and sometimes of mind, at present existing with regard to force, power and work; resistance and specific resistance; specific induction and total induction, or flux of force, &c. The use of the same letter, to denote the same physical quantity, will permit of the rapid examination of the homogeneity and correctness of formulæ.

Owing to our lack of knowledge as to the absolute dimensions of physical quantities, and with a view of economising symbols, the same letter may be used to denote quantities of the same physical nature but of different dimensions, or different physical quantities having the same dimensions. Thus I propose, for instance, to denote by the symbol W, the physical quality called energy, whether this energy be mechanical (work), thermic (heat), or chemical or electrical affinity. I represent by the same symbol the moment of a force or the moment of a couple, since this moment, the product of a force and a length, is homogeneous with work. A length and a coefficient of self-induction have the same dimensions (the coefficient of self-induction being defined in the electro-magnetic system) and will be represented by the same symbol L, an index being added in some instances to avoid confusion.

The name of each compound unit can be formed in the same way as the dimensions of the physical quantity to which the unit is to serve as common measure, conforming to the rules laid down by the International Committee of Weights and Measures, and extending these rules to units in which quotients figure. These rules consist in adopting a small Roman letter for each fundamental unit, and in using a prefix to denote the multiples and sub-multiples. The following are examples of the abbreviations adopted by this Committee :—

Centimetre... cm; square centimetre... cm^2; cubic centimetre... cm^3; centigramme... cg.

Together with M. Ch. Ed. Guillaume I propose to extend the use of the prefixes adopted by the Committee, and to adopt the two following *provisionally*.

M—mega—1,000,000

μ—micro—$\frac{1}{1,000,000}$

For example, the megagramme would be written...Mg; the microgramme would be written...μg.

In cases where there are quotients several notations are possible. Thus the C.-G.-S. unit of velocity is the centimetre per second, which may be correctly expressed in six different ways : centimetre per second, $\frac{\text{centimetre}}{\text{second}}$, $\frac{\text{cm}}{\text{s}}$, cm : s, $cm.s^{-1}$ cm/s. The notations (cm : s), ($cm.s^{-1}$), and (cm/s) seem to me equally correct. The last being the quickest, I propose to adopt it as the type of similar units. Thus, the industrial unit of pressure, the kilogramme per square centimetre, would be written kg/cm^2.

The choice of the symbols to be adopted is a more delicate question. The work should be confided to a special committee, or another Congress should be called before definitely settling the matter. I will content myself with giving a table,* subject to revision and modification, of the notations, symbols, and abbreviations which I propose for the most important quantities and units which concern the electrical engineer.

A committee† was appointed by the Congress to consider this communication, and the following resolutions were proposed and adopted unanimously at the last meeting of the Congress on September 12, 1891 :—

A. The Congress resolves that :

(1) Physical magnitudes shall be represented by Italic letters. (Proposed by M. Hospitalier.)

(2) Units shall be expressed in Roman type. (Proposed by M. Hospitalier.)

(3) Physical constants and angles by Greek letters. (Proposed by Mr. Preece.)

B. The Congress resolves that :—While recognising the following designations—*watt* for the volt-ampere, and *joule* for the volt-ampere-second, names agreed to by the International Congress of Electricians held in Paris in 1889, the practical electrical units shall be represented by the initial Roman capital letters of their respective names."‡

A ..... Ampere	O ..... Ohm
C ..... Coulomb	V ..... Volt
F ..... Farad	W ..... Watt
J ..... Joule	

C. M. Hospitalier having drawn up a system of notation, which, in his opinion, would be capable of denoting all important practical physical quantities without causing any considerable modification in present usages, we invite the members of the committee nominated by the Congress to be so good as to examine this system, which the committee recommends in a general manner, to put it to a practical test, and to publish as promptly as possible in the technical papers the results of this investigation, with a view to a common understanding, leaving to the next Congress the definite settlement of the notations to be adopted.

THE LAST OF THE "GREAT EASTERN."

The "Great Eastern" was built in 1853-59 by Mr. Scott Russell at Millwall, in the Isle of Dogs, from the designs of Mr. Isambard Brunel. The problem Brunel had been set to solve was the construction of a steamer large enough to carry sufficient coal for a voyage to India and back; coal which could be bought in England for less than £1 a ton costing £5 at the Cape. For this purpose he designed a vessel 680ft. long, 83ft broad, 114ft. broad over the paddle-boxes, 58ft. moulded depth,

* This table has been modified in conformity with the resolutions of the Congress.

† The committee nominated at the meeting of the Congress on the 10th of September consisted of Prof. Ferraris (President), Profs. Ayrton, Eric Gérard, Hospitalier, Kohlrausch, Lowenherz, Nichols, Quincke, Roïti, and Silvanus Thompson, Herr Strecker, and Mr. Preece; secretary, Mr. Carl Hering.

‡ The recognition of the watt and joule was due to a proposal of M. Hospitalier. The employment of initial capitals as abbreviations of the electrical units was proposed by Prof. Roïti.

and 18,915 tons gross register, to be propelled with both screw and paddles, and with a combined nominal horse-power of 3,000. The original plans were destroyed in the fire which occurred at Mr. Scott Russell's yard, and the actual dimensions of the ship were finally as follows:—Length, 693ft.; breadth, 83ft.; breadth over paddle-boxes, 120ft.; moulded depth, 58ft.; gross tonnage 22,500; registered tonnage, 13,335. On November 3, 1857, an attempt was made to launch her. This did not succeed, and for three months she defied all attempts to get her off the slips. At last, on January 31, 1858, she was successfully launched, broadside on, into the Thames.

Mr. Scott Russell adopted his wave line principle for the lines of the vessel, but to Mr. Brunel is due the idea of constructing her on the cellular system. She was built throughout of the best quality Lowmoor iron. The interior of the ship and the cellular hull were each divided into eleven separate water-tight compartments. The holds below the lower deck contained the machinery, boilers, stores, and coal; and

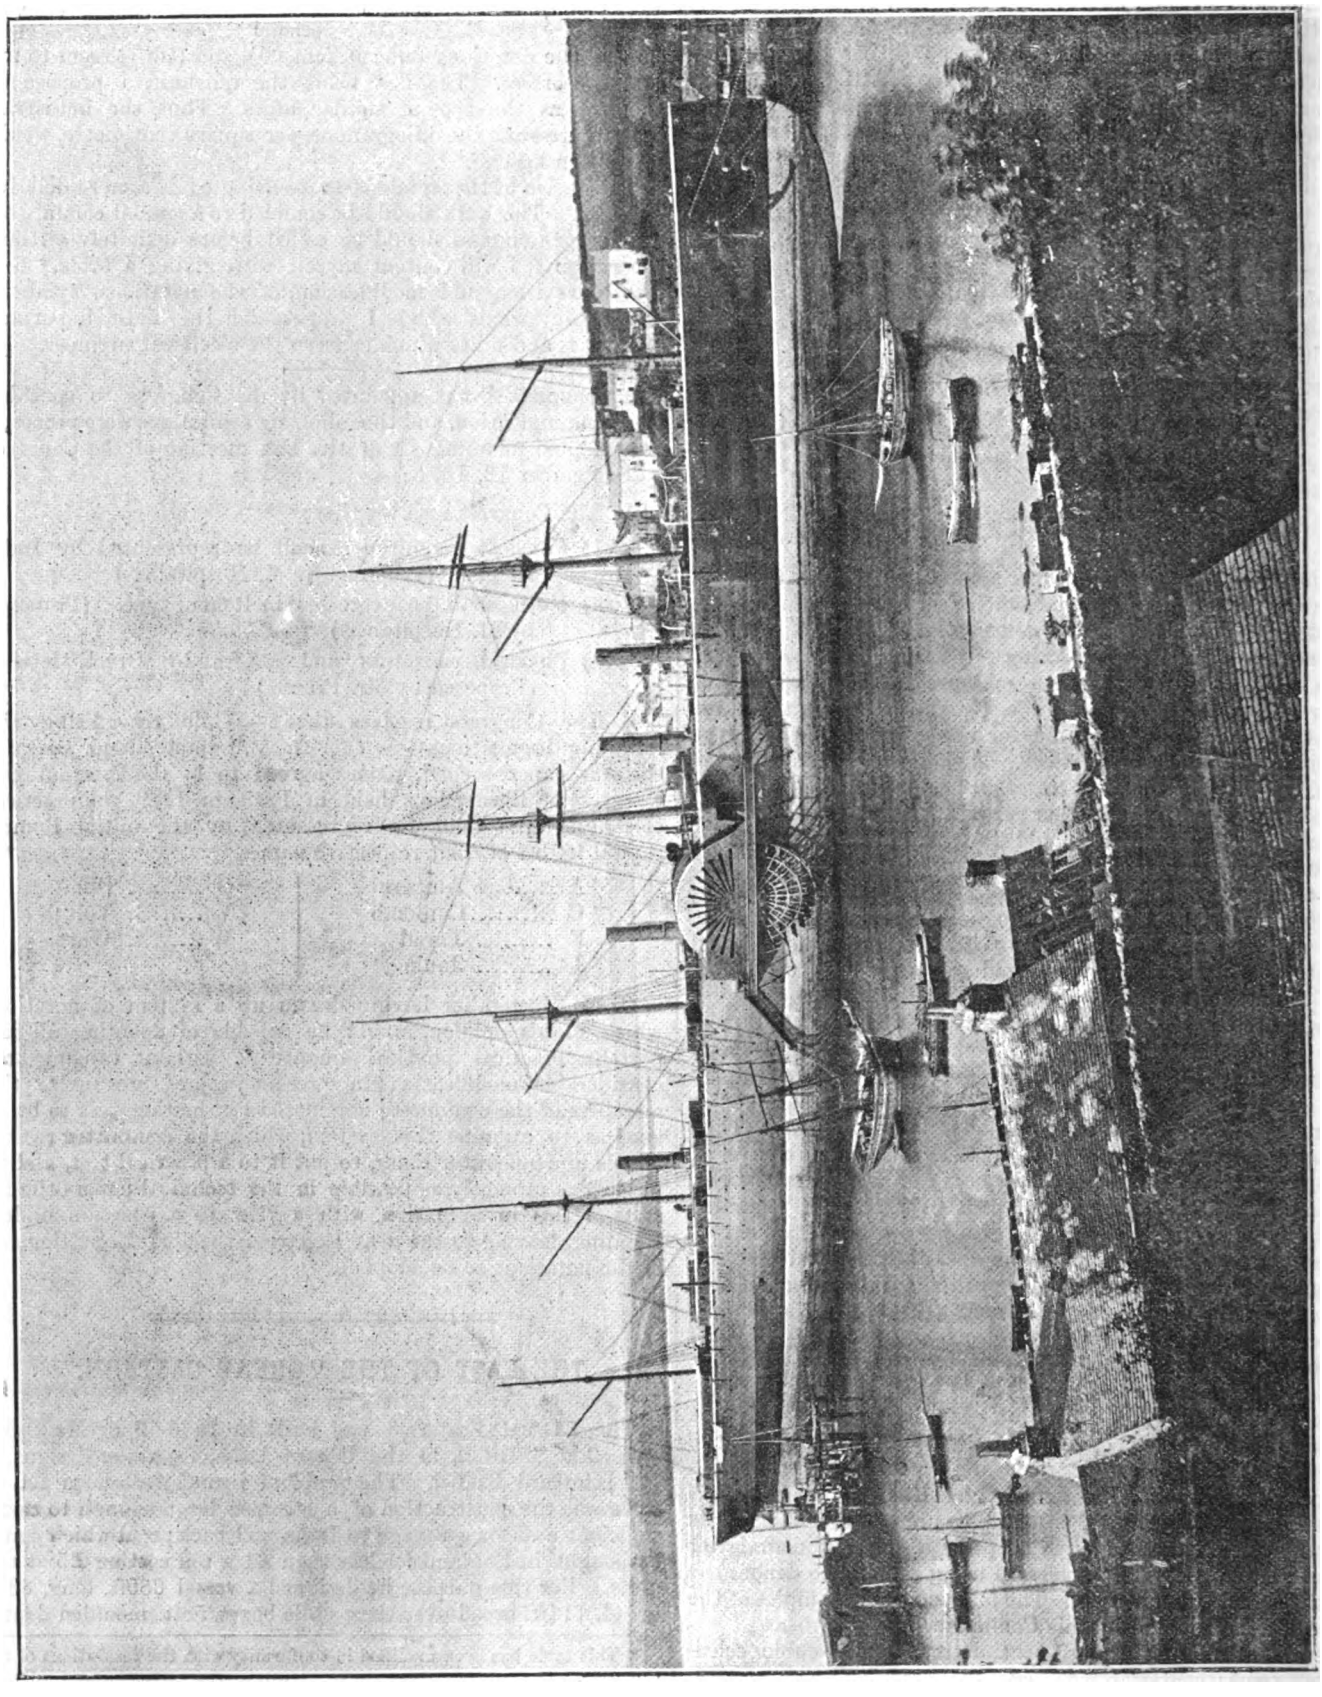

Fig 1.—The "Great Eastern" in Milford Haven, 1861.

Digitized by Google

the upper part, three tiers of decks all fore and aft, was appropriated for passengers, the lowest of these decks being about 6ft. above the water-line. The cylinders of the oscillating paddle engines were four in number, 74in. in diameter, 14ft. stroke. The paddle-wheels were 56ft. in diameter, and steam for these engines was supplied from four double-ended tubular boilers, containing 39 tons of water, and provided with 40 furnaces. The chimneys were only 6ft. in diameter, but being 100ft. high above the grate bars, there was an excellent draught. The cylinders of the screw engines were also four in number, 84in. in diameter, 48in. stroke. The propeller was four-bladed, 24ft. in diameter. Steam was supplied to these engines by six tubular boilers with 60 furnaces. The working pressure was 25lb. per square inch. Her calculated speed was 15 knots per hour. She was designed to carry 4,000 passengers, 5,000 tons of cargo, and 10,000 tons of coal, and if fitted up to carry troops alone she had accommodation for 10,000. The total weight of ship and engines was over 12,000 tons, and when fully laden with passengers, cargo, and coal, she would weigh 27,000 tons, and be at a draught of 30ft. She had five funnels and six masts.

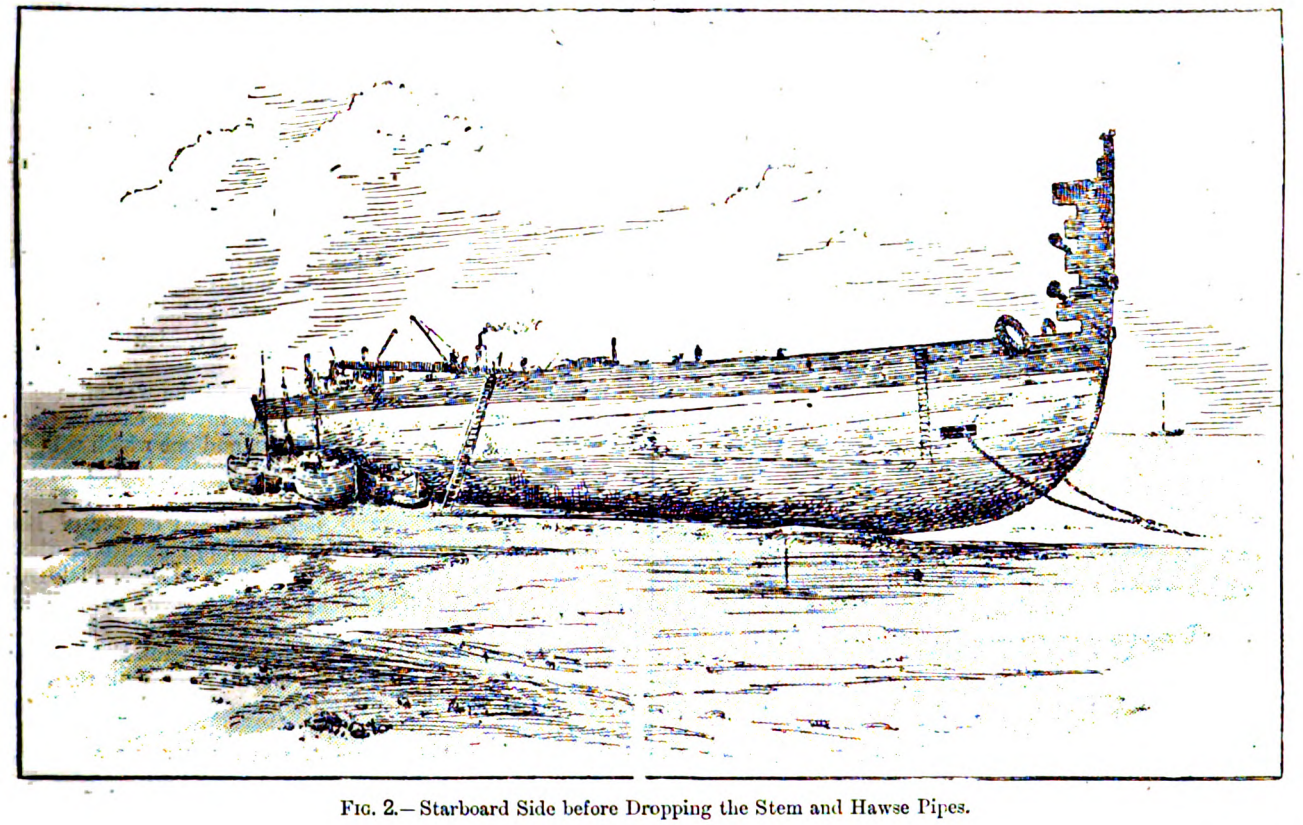

Fig. 2.—Starboard Side before Dropping the Stem and Hawse Pipes.

In June, 1860, she made her first ocean voyage to America, chiefly as a show ship, for she only carried 42 passengers out and 68 home. This voyage was a failure financially, although over 190,000 persons paid to visit her.

She was laid up at Milford Haven during the winter of 1860 61, and in the summer of 1861 she made several Atlantic trips, being finally much knocked about in a gale. She was then again laid up at Milford Haven during the winter, and made several runs between Liverpool and New York during the summer of 1862. In August of that year, on her voyage out, she struck on a rock off Montauk Point, the accident fully demonstrating the value and safety of the cellular principle of construction. In the summer of 1863 she made several voyages between Liverpool and New York.

Immediately after the formation of the Telegraph Construction and Maintenance Company, with Mr., now Sir, John Pender as chairman, its Directors offered to make and lay an Atlantic cable. The Atlantic Telegraph Company accepted their terms, and a contract was signed on May 9, 1864. The "Great Eastern" was chartered to carry the cable; and on July 15, 1865, left Sheerness for Valentia, under the command of Captain, now Sir, James Anderson. Mr. H. C Halpin was chief officer. Mr., now Sir, Samuel Canning was in charge of the expedition, and Mr. de Sauty was at the head of the electrical department, having Mr. Saunders as chief assistant. Mr. George Beckwith was her chief engineer. Prof. Thomson and Mr. C. F. Varley represented the Atlantic Telegraph Company, and Mr. Willoughby Smith the Telegraph Construction and Maintenance Company. On Sunday, July 23rd, the shore-end and intermediate having been laid by the "Caroline" and splices effected, paying out was commenced at six in the evening. As the cable was paid out several faults were discovered and remedied. On August 2nd, whilst picking up to recover a fault the cable fouled the ship and parted, 1,214 knots having been paid out at the time. After nine days of fruitless endeavours to regain the cable the "Great Eastern" was headed for home; and on August 20th anchored off Sheerness. A new length of cable was forthwith commenced, and on March 1, 1866, a fresh agreement was signed. On June 30, 1866, the "Great Eastern" left the mouth of the Thames again, under the command of Captain Anderson; and amongst those on board were Mr. Cyrus Field, Mr. (the late Sir) Daniel Gooch, Mr. Philip Rawson, and Captain Hamilton. On Friday, July 13th, paying out commenced; and on Friday, July 27th, the "Great Eastern" ran into Heart's Content Bay, and the first successful Atlantic cable was laid.

In 1868 the "Great Eastern" laid a telegraph cable from Brest to St. Pierre; in 1869 an Indian cable; and in 1871, 1873, and 1874 she successfully laid other Atlantic cables, and thus closed the mercantile career of the largest vessel ever floated, without even an attempt at the voyage for which she was designed and built, at a cost of £750,000.

Milford Haven was her final resting place, and there she lay idle for twelve years. On page 278 we give a view of the ship as she lay in Milford where the docks are now. From 1885 to 1888 she was chartered as a show ship, and visited Liverpool, Dublin, and Greenock. In 1888 the owners, Bath and Sons, Swansea, decided to break her up at Liverpool, and sell her as old metal. On November 20 to 25, 1888, every piece of timber, rope, metal, and furniture in her was sold by auction.

Digitized by Google

The work of breaking her up was begun in May, 1889. The task was completed on September 30, 1891, the operation occupying two years and four months.

We are indebted to our esteemed contemporary, *The Engineer*, for the loan of the blocks of Figs. 1 and 2, and for a large proportion of the text.

THE CRYSTAL PALACE ELECTRICAL EXHIBITION.

Although the machine-room and many of the stands in the naves were in a chaotic state on Friday last, the latter had been fairly well set in order on the following day, when the Electrical Exhibition was considered "open." We alluded last week to several exhibits which were already in a presentable state, and on a future occasion shall return to some of those which present special points of interest. One of the most prominent features of the machine-room is an 8-pole Kapp continuous-current 130 kw. dynamo, coupled to a Davey-Paxman triple-expansion engine. The arrangement recalls the 320 H.P. Schuckert dynamo at the Frankfort Exhibition. In the boiler-house is a new form of water-tube boiler by Davey-Paxman.

Many leading firms are conspicuous by their absence from the Exhibition. Messrs. Mather and Platt, the Silvertown Company, Paterson and Cooper, Allen, Holmes, Parsons, Goolden, Laurence, Scott and Co., Latimer Clark, Muirhead and Co., are among those who are either too busy, or have other doubtless good reasons, for saving themselves the expense and trouble of putting in an appearance. But quite as many unfamiliar names are to be found; and we hope that the young firms will find a reward for their efforts.

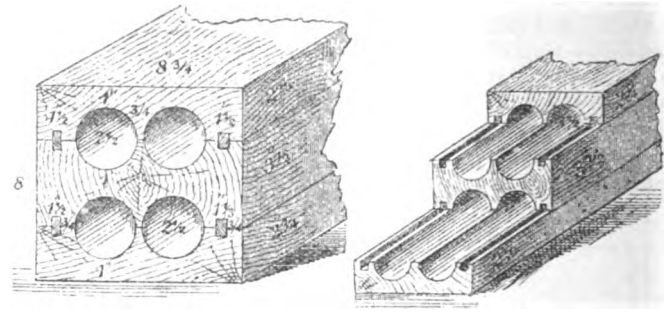
Messrs. Siemens Brothers are erecting five dynamos, of which four are to be driven by Willans engines. One of these is of the open type, built in accordance with the wishes of certain customers who think that what is out of sight is out of mind. While Messrs. Willans and Robinson cut away their casing, Mr. Raworth builds up oil guards, until at a superficial glance there begins to be a resemblance between the rivals. A very good show of gas engines will be found in the machine-room.

A very neat system of lubrication is to be seen at the Brush Electrical Engineering large stand in the South Nave. The pedestals of the dynamo are arranged as oil reservoirs, and supply two little rotary pumps, on the Root principle. These are driven from a light shaft mounted on the bed-plate, and belted to the dynamo shaft. The delivery pipes are led to the bearings, and supply both the top and the bottom of the journals by two separate pipes, provided with regulating valves. The oil is thus forced into the oil-ways under considerable pressure. The drain pipes lead from the bearings, and allow the oil to fall in a stream into cups attached to the side of the pedestals. A strainer is placed to receive the flow, and the oil passes back into the reservoir. "A visible drain" is thus substituted for a "visible feed," and the one is quite as satisfactory as the other for the purpose of ensuring a regular and continuous supply; but the "visible drain" has the great advantage that the lubricant can be forced into the bearings under pressure, this being impossible with a visible feed, unless the complication of more or less fragile glass tubes is resorted to.

The latest form of Mordey transformer differs only from the earlier patterns in the details of its mountings. Four terminals are provided for the secondary, which is wound with two similar circuits, thus allowing the consumer to take 100 volts or 50 volts. A switch is placed on the primary to enable fuses to be replaced. An ingenious "brush" is shown on an alternator. It consists of a long, limp, flat roll of wire gauze hung over the collector, making contact over a whole semi-circle. It is made fast to a terminal at one end, and the other is kept taut by a weight. These have not been largely employed by the Brush Company, but where they have been tried they work in a satisfactory manner.

Among the minor exhibits which were in a complete state on Friday last was that of the British Stone and Marble Company, who show numerous specimens of their Petrammite. This is a composition consisting almost entirely of silica, and resembling white china. The two important features of this material are—first, that it is a very good insulator, does not condense moisture on its surface, and is not affected by continued immersion in water; and, second, that it does not shrink, or warp, or twist in baking, like all porcelains. The material is moulded under pressure, and screws placed in the mould become surrounded with it, and thus excellent threads are produced, and accuracy of position of the holes may be ensured. Switch bases and lamp-holders of numerous patterns are shown.

Near the last exhibit are some specimens of the Macdonald conduit. The conduit is made of timber in lengths of about 14ft., with holes 2½in. in diameter. The sections, as shown in the illustration, are tongued with fillets, which, it is claimed,



keep out water. This conduit has been used for six years in Philadelphia. For telephone, and, possibly, for telegraph, work this conduit may be useful; but in this country it is doubtful whether it would be suitable for electric light work. Creosote is an admirable preservative for wood, but is most injurious to many kinds of insulating materials. Wood, treated in any way, is one of the worst materials for opposing a creeping discharge. Nor is this conduit suitable for use with lead-covered cables, since creosote attacks lead, and even alloys of tin are not entirely exempt from corrosion by the organic acids that are generated.

Whether there is much that is new in the way of machinery and apparatus can be discovered on further examination; an interesting feature of the Exhibition, and one which will, doubtless, be appreciated by the general public, is the display of ornamental fittings. In this department, again, there are many absentees. Where is the burnished copper of Benson, the massive brass work of Verity, or those gasfitters who have more recently turned their attention to electric fittings, such as Hulett and Strode? Why has M'Geoch, so well known in Glasgow, failed to tempt some London business? The Keys Company made a good show at the St. Pancras Exhibition; and no stand was more attractive on that occasion than that of Messrs. Crittall and Co., but they are not to be found even in the catalogue.

The catalogue is another feature of the Exhibition which ought to be thoroughly appreciated by sightseers. The exhibits are divided into sixteen sections, designated alphabetically, and each of these is prefaced by short, popular articles, which are the work of Mr. H. J. Dowsing. We have only one fault to find with it. We are sure that the article on "Electricity in Surgery and Therapeutics" would not have been allowed to pass without a word of warning against imposture, if the writer had known that it would be faced by a full-page advertisement of an impudent quack.

RADIATION OF ELECTRIC ENERGY.*

BY FRED. T. TROUTON.

The tendency of electric science has gradually been to more and more direct attention away from the wire in the case of electric currents to the surrounding medium as the primary seat of the phenomenon.

To start a current in a wire we now know really means to throw the medium occupying the surrounding space into some peculiar state, of the character of which we as yet know nothing for certain; but of the reality of this state, nevertheless, we feel

* The conclusion of a course of lectures delivered in Inverness, December, 1891, under the auspices of the "Ettle's Trust."

Digitized by Google

sure, for one thing it requires energy initially to produce it, the amount necessary depending on the character of the medium and when the peculiar state ceases; or, as we say, when the current is stopped the energy, which has meanwhile remained stored in the surrounding medium, appears in an otherwise undue continuation of the current.

When the direction of a current is reversed we must suppose that there is something in this peculiar state of the medium which can be reversed, so that the medium surrounding a current must be affected with a definite directedness, or "set" of some kind in one direction, this "set" being reversed when the current is reversed. With alternating currents these reversals follow each other with regularity; and could we only see with our eyes what was going on in the surrounding medium, we would see the medium near the wire vibrate, first with a "set" along the wire in one direction, then in the other; next we would observe these disturbances spreading outwards from the wire one after the other into space, very much like what we see when we drop a stone into water. It is to the consideration of these electric waves we propose for the moment directing our attention. They constitute at the present time an important, though one of the latest branches of electricity. But before doing so it may perhaps be not amiss if we consider shortly the subject of waves in general.

It is quite a mistake to think that the medium itself travels forward with the waves. For instance, when waves pass over the surface of deep water, that is to say well away from the disturbing influence of the shore, the water moves up and down, but does not go forward. This may be seen to be the case by watching a small floating object; it moves up and down with the waves, but does not go forward. One can send waves along a stretched rope by oscillating one end, and here it is evident the only motion forward possible is that of the wave.

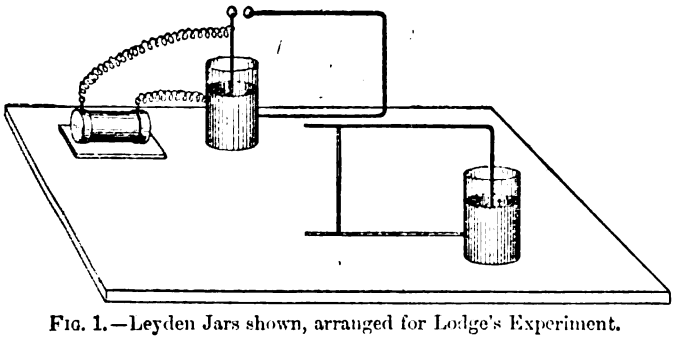


Fig. 1.—Leyden Jars shown, arranged for Lodge's Experiment.

The distance, apart of the wave crests, depends on how far a disturbance gets away before the next starts—that is to say, on the rate a wave travels. And since the rate is enormous, in the case of electric waves, the disturbances must succeed each other very rapidly, if the distance from crest to crest is to be small and at all within our capabilities of experimenting with. When the disturbances occur every second the distance from crest to crest is 180,000 miles, for that is the stupendous distance these electric waves are found to travel in one second.

The method at present employed for getting alternating currents of sufficient rapidity is well illustrated by the following experiment, due to Prof. O. Lodge (Fig. 1). In it the alternating current is obtained automatically, by utilising the natural tendency to oscillate to and fro, which a current in an incomplete circuit has. Such an arrangement can be produced through the following circumstances:—A considerable amount of electric energy, comparatively speaking, is able to be stored up by the device (now over a hundred years old) known as the "Leyden jar." It consists essentially of two metal plates placed near each other. This is effected in the Leyden jar by a coating of tinfoil on the outside and another on the inside of any ordinary glass vessel. Into such an arrangement a current can be run, and its energy kept stored there, apparently in some strain in the medium separating the metal plates. But as soon as the metal plates are connected by a wire, the stored energy is set loose in the generation of a current. This current will alternate, should the wire not be very long, and the resistance to the current not very great; and consequently the heat produced on the passage of the current in the wire be insufficient to completely account for all the energy stored in the jar. That is to say, the surplus energy will cause the current to overrun itself, and we will have the medium between the plates again strained almost as much as before, but in the opposite direction; again, there will be a current, but now in the opposite direction to the first one, and so on, the currents oscillating backwards and forwards until all the energy is exhausted, in this respect resembling the pendulum. The pendulum, when drawn up to one side and let go, will pass by the position of rest and over to the opposite side, provided the resistance to its motion is not too great, as it would be if the pendulum were placed, say, in treacle.

After this fashion, then, alternating currents of great rapidity are obtainable, by what may be considered an automatic arrangement, as contrasted with a dynamo; and at each rush of electricity from plate to plate, a wave starts out from the connecting wire and spreads outwards into space.

So much for the means employed for originating the electric waves; next we will consider how this radiation is to be received and detected. In fact, what is to be our electric eye, as Sir William Thomson calls it, which is to perceive these waves? It depends essentially on the principle of resonance. This principle is well illustrated by a common swing. When shoves are given to it at the right intervals, so as to suit the period of swing, the swing quickly starts up, absorbing energy each push. If it is pushed irregularly it is quite otherwise.

Two little swings of the same length (Fig. 2) suspended from either end of a horizontal rod illustrate this well; being of the

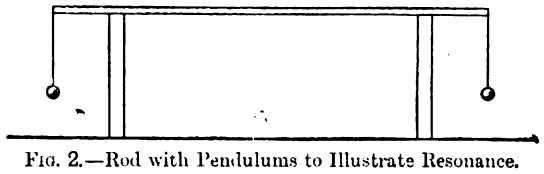

Fig. 2.—Rod with Pendulums to Illustrate Resonance.

same length they take the same time to complete each swing. Now if one of them be set going, we soon find the other beginning to swing also.

Each little jerk sent along the rod is just at the right interval after the last to give a help in getting up the swing. Now this obviously requires both to have the same period of swing; and, indeed, if we alter this by shortening or lengthening one of them, we soon see that the ability to absorb energy is destroyed—no swing is produced.

Thus we perceive that a receiver of the electric pulsations would be of the same size as the radiator. In Prof. O. Lodge's experiment, a jar of the same size as that of the radiator is used, the tinfoil coatings being joined up by a wire of the same length. So that, if we start the alternating currents in the radiator by charging up the jar till a spark occurs in the break left in its connecting wire, we know that the impulses it sends out are just at the right intervals apart to set our receiver also going; because the time which would be taken by the current to alternate is the same in both, and thus each successive impulse arrives at the receiving circuit just at the right instant to find a current going in the same direction as it would itself cause, the final result being a greatly-increased swing; so much so that the pressure in the jar increases sufficiently at last to cause quite a bright spark to pass from the little end of tinfoil projecting from the inside plate of the jar to the outside for the purpose. The necessity for the time of alternation being the same in both is seen on moving the vertical wire, which connects the two horizontal wires of the receiving jar to either right or left, for no spark can then be got in the little overflow path.

It was after this fashion that, four or five years ago, Prof. Hertz, of Bonn, constructed, for the first time, an electric radiator and receiver, and thereby gave us the means, and showed us how, to deal with electric radiations. Not that we knew nothing about electric radiations before then, for Maxwell had even calculated the speed they would be found to travel at; but until we could, so to speak, actually handle them, it necessarily remained outside the pale of experimental knowledge.

LEGAL INTELLIGENCE.

National Telephone Company v. John Milne and Son.

In the Dundee Small Debt Court, on Tuesday, before Sheriff Campbell Smith, the National Telephone Company (Limited), Dundee, sued John Milne and Son, flour and provision merchants, Shore-terrace, Dundee, for £8. 10s., being the rent or subscription, payable in advance, for the year from November 15, 1891, to November 15, 1892, for the use of telephone wire and instrument. Mr. Robert Still, solicitor (Messrs. Thos. Thornton, Son and Co.), on behalf of the pursuers, stated that the defence advanced by the defenders was that sufficient service had not been rendered during the past year. That, however, was a defence which had been trumped up now that a disagreement had occurred between the parties. The lease, which he put in, was for three years, from November 24, 1890. About the month of October, 1891, John Milne and Son gave notice that they were to discontinue the use of the wire at Martinmas, 1891. It was intimated, however, by the Company that such notice could not be accepted, because the agreement was still current, and would not expire until Martinmas, 1893. In reply to that the defenders said, "We will not pay you another farthing. Every time we ask a connection it looks as if we were asking a favour, and this we have mentioned to your canvasser." The Telephone Company pointed out that any complaint which might have been made ought to have been made to the proper quarter, and it would have received the most careful consideration. Messrs. Milne in their next letter stated that "If you endeavour to coerce us to make payment for the wire we have now ceased to use, and for which no value could be rendered, it will be our purpose to let the facts be known through the Court by the public Press." That letter alone, Mr. Still contended, showed that there was an attempt on the part of the defenders to be vindictive, and he hoped his Lordship would not be a party to such vindictiveness. Mr. Still then read the conditions of leave between the Telephone Company and Messrs. Milne and Son, among which was the following:—"The Company shall not be liable for any loss or damage occasioned by the interruption of telephonic communication from any cause whatever."

Mr. URQUHART, for defenders, admitted that a contract had been entered into, but at the same time he declared that the service given by the Company to Messrs. Milne and Son had been radically bad. At times it was utterly impossible to get a connection through the Central Office with any other subscriber, and at the very period of the day when his clients most desired a connection with their customers they never could get it. The Telephone Company was very much afraid that the facts concerning the action should get into the daily papers. Mr. Urquhart said that Mr. Still had attempted to show that the complaints now put before the Court had been suddenly trumped up. That, however, was not the case. Messrs. John Milne and Son were large merchants, and had been in business for a great number of years. They had no wish whatever to get out of their obligations. More than that, it was of the utmost importance that a firm like theirs should have every facility they possibly could for communicating with their customers. It was simply and wholly because they could not get the necessary services out of the Company that they proposed to cease their connection with it. A telephone which gave bad service was of no practical use to them, and they objected to be blackmailed. The agreement was perfectly one-sided, being totally in favour of the Company. If he could prove that the pursuers had not got their part of the contract he thought his clients were quite at liberty to depart from their obligations in the matter. For a long time the service had been bad, and any attempt to get it improved failed. Instead of getting improved service they got a great deal of impertinence. It was quite a proverb in Dundee that the Telephone Company was responsible for half the profanity among the Dundee merchants. Mr. Urquhart said that Messrs. Milne and Son did not wish to deprive the National Telephone Company of their rights. There was an important clause in the agreement which allowed subscribers at the end of one year to give up the use of the telephone. That clause was as follows:—"The subscriber shall be entitled to cancel this agreement at the end of the first year on giving the Company six months' previous notice in writing, and paying an additional half-year's subscription." Mr. Urquhart contended that the Company had not got an efficient staff of servants. If the telephone were properly managed and the service complete, it would be a very valuable adjunct to his clients' business. Instead of the case being a trumped-up one on the part of Milne and Son, a considerable time ago—nearly nine months—they wrote to the Telephone Company saying that they had had at one time a mind to make the Telephone Company refund the money on account of the unsatisfactory service received.

The SHERIFF said the case raised a very difficult question. He doubted very much if it was a suitable one to be disposed of in the Small Debt Court. He could go far enough to be able to express an opinion from what he had heard that the case could not be disposed of that day. He was quite clearly of opinion that the case could not be disposed of without proof. In the first place, pursuers had no case without proof, because the documents signed by Milne and Son agreeing to be subscribers had been signed by one party, and such a document was not a contract by itself. It required proof that it was acted upon to make it a contract. The other part of the matter seemed to him to come to this, that Messrs. Milne and Son agreed to pay for the use of the wires for three years. They became dissatisfied because they could not get sufficient service, and they therefore wanted to get quit of the contract. The real case, therefore, that arose was whether the pursuers could prove a breach of contract against Milne and Son, or whether Milne and Son could prove a breach of contract on the part of the Telephone Company. If the Telephone Company could prove that Milne and Son had no more obstruction to the carrying out of their business by telephone than might be naturally expected, then the Telephone Company would succeed; but, on the other hand, if Messrs. Milne and Son could prove that the Telephone Company neglected to serve them—that they wilfully did it—and kept an insufficient staff, with the result that they could get no proper service, the case would assume a different complexion. His Lordship allowed proof, saying that he would fix a diet at an early date.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *December* 31, 1891.

Block Signals.—The holidays have tended to make electrical news somewhat scarce. Perhaps the subject most immediately before the public mind is the application of electricity to block systems for railways. The terrible accident on the New York Central Railway a short distance from this city on Christmas Eve forced the matter of safety precautions on the unwilling attention of the officials of that road. The New York Central Railway has been experimenting for some time on various block systems, among them the Sykes, that of the Union Switch and Signal Company, and the Hall. The Sykes system is to be introduced, it is said, as far as Poughkeepsie immediately, and it is probable that one or both of the other systems mentioned will be installed beyond that point.

Storage Battery Traction.—The subject of electric road carriages seems to be agitating the fertile brains of some of our American inventors. Two separate attempts have recently been made—one in Chicago and the other in Boston—to put this particular sort of electrical traction into practical form, with the usual degree of success and improbability of any considerable results. *Apropos* of this, not very far out of New York, and on the main line of the Pennsylvania railroad, the traveller can see rising close along the side of the track a four-storey building, of imposing dimensions, crowned by a cupola; a great sign on the front bears the legend, "United Electric Company"; on an oval track immediately in front of it stand—forming their own funeral procession—the cars that have been taken off the Fourth Avenue line in this city. This lugubrious vision would deter most men from walking in a similar path, but it has not prevented the recent organisation of a Storage Battery Traction Company with half a million dollars capital.

The Green Electric Railway Patents.—We are beginning to hear a little more of the Green Electric Railway Patents, of which I wrote you some time since. That Green was one of the early workers in electric railroading is very certain; but from what can now be ascertained it seems probable that his invention followed closely in the line of the group of attempts at electric traction that date back to 1850. Few electricians attach any great importance to the patents for that reason. They may, however, have the effect of damaging what slight value some of the later broad patents might be supposed to possess. It does not seem that any more can be said for Green than that he was a most ingenious and persistent inventor, whose work serves as a connecting link between the electric railroad of to-day as elaborated largely by Siemens, and those older experiments which are well-known to many electricians. Taken as a group, electric railway patents are rendered of questionable value in view of the fact that so many experiments on the subject were made long before the invention of the dynamo.

Institution of Civil Engineers.—Saturday, January 2, was the 74th anniversary of the establishment of the Institution of Civil Engineers. Founded by six young men then beginning their engineering life, it has grown to be one of the largest bodies in the Kingdom, numbering 6,139 of all classes. In the Royal Charter of Incorporation, granted to the Society in 1828, its object was stated to be for the general advancement of mechanical science, more particularly in its application to civil engineering.—Amongst the Associate Members elected at the ordinary meeting on Tuesday last was Mr. H. J. S. Heather, B.A.

CORRESPONDENCE.

SOME EXPERIMENTS ON SECONDARY BATTERIES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your last issue you gave a short account of some experiments on secondary batteries as made by Mr. Robertson, the results of which seem dubious to me, on the ground that the working admits a considerable source of error.

From your account it appears that you used a low-resistance voltmeter, an instrument which would require a fairly large current. This is no objection when used with ordinary large accumulators, since they, having a very low resistance, will supply the required current, and yet give a potential difference practically equal to the E.M.F.

But when the same current is taken from a miniature cell, whose resistance is far higher, there is a great danger that the potential difference will differ appreciably from the E.M.F.

Nor is this all. The "capacity" (or power to maintain a current) of such a miniature cell is very small, so that it soon runs down if the current exceeds a certain value.

It seems to me that these facts account for most of the results given; but as I am merely surmising, I only point out three things:—

1. All the E.M.F.'s given are low.
2. The cells seem to run down almost at once in all trials.
3. That in trial of cell B the addition of hydrogen dioxide does not at first reduce E.M.F., but only when the current has been running a short time.

These three agree with what I should expect if my suggestion be true. I have worked with cells for many years, and never got E.M.F.'s so low as those quoted unless the cell was in need of "charging."—Yours, &c., W. HIBBERT.

14, Goldhurst-terrace East, South Hampstead, N.W.,
January 7, 1892.

P.S.—Dr. Gladstone and I hope to read a Paper on the E.M.F. of such cells at the next meeting of the Physical Society. Our results are practically in direct opposition to those obtained by Mr. Robertson.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Mr. Hibbert has favoured me with the substance of his letter to you with reference to the experiments on secondary batteries described in your last issue; so I take the opportunity of replying at once.

My original experiments on the effect of hydrogen dioxide on E.M.F. were made with a Thomson high-resistance galvanometer, with considerably over a megohm in series with it; but one day, when repeating the experiments, I found, to my surprise, that, although, as Mr. Hibbert points out, small cells, on a low-resistance voltmeter, naturally ran down quickly, still the effect of hydrogen dioxide in hastening the running down was unmistakable.

With reference to the E.M.F., I have never calibrated the voltmeter for use with the small cells; but, judging by results obtained when using a galvanometer, I should say 1·7 divisions on the voltmeter was equivalent to about 1·9 volts.

The voltmeter was only used to get a deflection, and I think Mr. Hibbert leaves out of consideration that, though cell C contained two lead plates, it was only the E.M.F. of the couple formed by the interchanged plates which was annulled, that of the other lead plate and the positive remaining much what it had been until these plates were interchanged, when it fell immediately as before.—Yours, &c.,

G. H. ROBERTSON.

30, Hemstall-road, West Hampstead, N.W.

PLATINOID v. COPPER FOR D'ARSONVAL GALVANOMETERS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I should hardly feel justified in trespassing any further upon your valuable space in the above question except for the fact that Mr. Mather in his reply to my previous letter makes a few statements, which, to the ordinary reader, must give an incorrect impression of the working of the system of measuring instruments at Thames Ditton, and which therefore call for a few words of explanation. I have namely shown that the existing copper coil in the ampere-galvanometer involves variations of resistances of ·04 per cent per °C. only, when currents of 200 amperes and upwards are measured (of course, by far the greater part of the work falls within this range), and since ·023 per cent. of this is balanced by the main rheostat, the errors that could occur *in the scale-readings* would not exceed ·017 per cent. per °C. if the proper corrections for temperature were neglected altogether. I have further pointed out that, with the platinoid coil proposed by Mr. Mather, the value of the galvanometer-current corresponding to any given deflection, on the determination of which all the measurements depend, and which is now found with extremely great accuracy (·011 per cent. + the error in the observation of the deflection), could be only roughly measured. According to the resistance in the standard cells at present in use, the error in this measurement might become as great as ·14 per cent. Now, considering how small the trouble is to make the necessary correction for temperature, and remembering that the real measurement is quite independent of this correction, Mr. Mather's latest arguments have not made me alter the view I have already expressed. It is not a question of getting rid of temperature-corrections altogether, and the proposed saving in labour would, as shown, be too dearly paid for.

My chief object, Sir, in again addressing you is, however, to point out that the real measurement in Captain Sankey's system is, for the amperes:—

$$C = \frac{R_A + G}{m R_1 + G} \frac{e}{B} \text{ (formula 2 in the Paper);}$$

and for the volts:

$$E = \frac{r}{r_a} \frac{R_v + G}{m R_1 + G} e \text{ (formula 4 in the Paper);}$$

and it is in these measurements we claim to work within $\frac{1}{5}$ per cent., and not in the ordinary scale readings as supposed by Mr. Mather; I am, therefore, not concerned with that part of his argument which is founded on the latter supposition, although I may say that I fully agree with him, that even the scale-reading alone, when care is taken, may come very near to the ·2 per cent. But, looking at formula 4, $R_v + G$ was the resistance of the galvanometer-circuit whilst the mean reading from the dynamo trial was obtained, $m R_1 + G$; the corresponding resistance when this mean reading was reproduced by the use of the standard cell (of E.M.F. $= e$), r/r_a is the relation between the total and a portion of the potentiometer-rheostat. Now, as the two fractions of resistances are obtained by bridge measurements, their product will be known within ·07 per cent.; and, allowing 1°C. as the maximum error in taking the temperature of the cell, in order to have the result within ·2 per cent., the errors of reading must be within ·05 per cent., which is easily possible. But with the platinoid coil the error in $R_1 + G$ might, as admitted by Mr. Mather, be ·14 per cent., which is more than we can afford.

Let me remind Mr. Mather, when he says, "It is no use calibrating an instrument to an accuracy immensely greater than that to which its scale can be read," that it is exceedingly troublesome to balance with a galvanometer, on which the smallest visible deflection covers the whole permissible error (unfortunately, with the platinoid coil, it would cover even a little more); it causes waste of time and ruin to the standard cell.

The error mentioned as ·4 per cent. in connection with the potentiometer-rheostat (the proportion r/r_a above) does not, as Mr. Mather says, apply with constants ·05 and ·1, but with the former only—applying to the range 1·7 to 8 volts. But in the real measurement (formula 4) it does not exist, for the resistance r_a is of course measured with the galvanometer-circuit closed, and thus the true fall of potential ascertained.

With reference to the danger, mentioned by me, of the heating of the resistance-coils in series with the platinoid coil on account of the comparatively heavy current used, I highly admire the exact way in which Mr. Mather has dealt with this question:

Digitized by Google

The maximum heat produced in one coil (400 ohms) is ·7 calories per hour; weight of metal in coil, 56·7 grammes; hence 1°C. rise of temperature in 7¼ hours if no heat escaped.

One can, of course, have resistance-boxes made in which the metal of the 400-ohm coil weighs 56·7 grammes; but in the ordinary commercial patterns the weight of that metal (when in G.S.) is 4·3 grammes, 1°C. rise would be attained in $4{\cdot}3/56{\cdot}7 \times 7\frac{1}{4}$, *i.e.*, in 0·54 hour; and after making due allowance for the heat which will escape, we shall have enough left to more than balance the almost infinitesimal advantage introduced by the platinoid. Errors of the kind here mentioned should be strictly avoided, as they are very difficult to detect.

Mr. Mather has also dealt with the question of the weights of the two coils of different metals. His assumptions as to the actual properties of the existing copper coil are, however, incorrect, and the same is necessarily the case with the conclusions.—I am, &c.,

F. V. Andersen.

January 12, 1892.

THE ASSOCIATION FOR THE IMPROVEMENT OF GEOMETRICAL TEACHING.

TO THE EDITOR OF THE ELECTRICIAN.

Sir: The new departure of the Association, to which I alluded at the close of my former letter, viz., the extension of the field of work to include all branches of Elementary Mathematics and Mathematical Physics, was not taken with the same unanimity which marked the proceedings, as long as they were confined to Elementary Geometry. Although most were ready to admit that there was much to be done both in reforming the methods now in use in teaching Arithmetic, Algebra, Trigonometry, and Dynamics, and in popularising the ideas of Maxwell and Clifford on *vectors*, it was doubted by some whether the organisation of the Association would be found suitable for the purposes advocated. The chief objection to the step was well put by one of its opponents (who, however, has continued to be one of the most loyal workers for the Association): "The great bond of union among them as an association was that they had a grievance—Euclid forced on them by the public examinations. If they extended their operations to subjects in which no grievance existed there would be so much diversity of view, and their efforts would be so far less definite that they would be scarcely likely to succeed in getting attention. . . . If they went into certain other subjects, they would not have common interests and common views."

Experience has shown that there was much force in these objections, though fortunately they did not prevent the proposed extension; and it will be instructive to examine how far the Association has been able to carry out its revised programme, which it was to effect—

(i.) by the reading of Papers or raising discussions at meetings of the Association;

(ii.) by the appointment of committees to report on existing defects in the usual methods, order, range, &c., in teaching special subjects, and the expediency of drawing up syllabuses or text-books of such subjects;

(iii.) by the drawing up of such syllabuses or text-books by committees or individuals selected by the Association.

In (i.) it has been fairly successful, as a glance at the following list of Papers published with the annual reports may show:—

1883. "The Teaching of Elementary Mechanics." (W. H. Besant.)
"Notes on the Teaching of Elementary Dynamics." (Prof. G. M. Minchin.)
"The Basis of Statics." (Prof. H. Lamb.)
1884. "The Discovery and the Geometrical Treatment of the Conic Sections." (Rev. C. Taylor.)
1885. "Elementary Mechanics." (Prof. R. W. Genese.)
1886. "The Correlation of the Various Branches of Elementary Mathematics." (R. B. Hayward.)
1887. "The Teaching of Modern Geometry." (Rev. G. Richardson.)
"The Modern Treatment of Maxima and Minima." (Rev. J. J. Milne.)
"Geometry from an Artist's Point of View." (G. A. Storey, A.R.A.)
"Note on the Nine Point Circle." (E. M. Langley.)
1888. "The Recent Geometry of the Triangle." (R. F. Davis.) With Notes by E. M. Langley, and R. Tucker.
"The Multiplication and Division of Concrete Quantities." (Prof. A. Lodge.) With notes by Mrs. Bryant.
"Some Principles of Arithmetic." (W. Bell.)
1889. "The Vices of our Scientific Education." (Prof. G. M. Minchin.)
"Horner's Method." (R. B. Hayward.)
1890. "A New Treatment of the Hyperbola." (Rev. C. Taylor.)
"The Teaching of Plane Trigonometry." (G. Heppel.)
"Some Geometrical Theorems." (E. M. Langley.)
"Statics and Geometry." (Prof. G. M. Minchin.)
"Isoscelian Hexagrams." (R. Tucker.)
1891. "On the Use of the Term 'Abstract' in Arithmetic." (Miss Wood.)
"The Foundations of Geometry." (E. T. Dixon.)
"Some Notes on 'Statics and Geometry.'" (E. M. Langley.)
"Sketch of the Life of the late A. J. Ellis." (R. Tucker.)

Of these, perhaps, the most interesting to the general reader would be Mr. Storey's, which gave an easy treatment of some of the simpler problems in perspective, and Mr. Davis's, which, I believe, introduced many of its readers for the first time to a connected view of an interesting group of recently discovered theorems, and showed that the triumphs of the older methods of geometry were not yet exhausted. But there is no doubt that the one which takes the most advanced views of future developments in mathematical teaching is that entitled "The Correlation of the Various Branches of Elementary Mathematics," by Mr. R. B. Hayward. This is, unfortunately, out of print and scarce. It goes far in the direction of some of the changes advocated, as I gather from the "notes," with editorial approval, by Mr. Heaviside. Perhaps, Sir, you might see your way to doing a service to the cause of progress by allowing a reprint of it to appear in your columns.

The work of the committees has, on the whole, been slow and unsatisfactory. Those for geometrical conics and for higher plane geometry completed their work with a fair amount of despatch. The former, though it contributes nothing to the method of teaching the subject, is a well-ordered sequence of propositions, which has been adopted by Messrs. Cockshott and Walters, as the basis of an excellent text-book (Macmillan). The latter supplies a good selection of elementary propositions, adapted for school use, in higher plane geometry, and is likely, I understand, to be also adopted as the basis of a text-book. But the divergence of views of members of the Committee on Mechanics has prevented much progress being made with its work, and that on solid has done very little beyond the circulation among members of a draft syllabus, which it seems impossible to get either mended or ended. To my own mind this method of bringing out syllabuses seems rather a costly mistake on the part of the Association; and that the Council would do well to abandon it on the completion of those now in progress, and to develop much more extensively the method, adopted on a small scale during the past year, of circulating pamphlets or fly-leaves in which individuals may bring before their fellow-members various points of mathematical teaching to which they wish to draw attention. The Association may thus long serve as a useful bond among mathematical teachers who wish to keep alive to every possible improvement, whether in such humble matters as a simpler presentation of some old-world theorem, or the introduction into school courses of methods made possible by recent developments of their science.

I should like to say a few words as to your remark on the "stubborn conventionalism of the modern schoolmaster, who pleads that he cannot make any change because of the Universities." I do not think the "modern" schoolmaster is more "conventional" than his predecessors, and I feel certain that he is less "stubborn." Unfortunately, his plea as to the Universities is only too sound a one, Oxford in particular issuing term by term in its pass geometry papers artistically finished specimens of what an examination in geometry should not be. These consist almost always of book work only, without a single question on the subject matter, and without a single exercise. It is to be hoped that the Council of the A. I. G. T. may bring some further influence to bear on the examining authorities, and endeavour to get Papers set more in accordance with the spirit of the report adopted by the Hebdomadal Council. At present the Papers are

Digitized by Google

direct incentives to "cram" in its worst form. Nor is the evil confined to those students thus directly influenced. In the words of an Oxford graduate: "From the ranks of the passmen are recruited a large number of schoolmasters. That these men should receive, in an education professedly liberal, a mathematical training so inadequate in amount, and so imperfect in method, is to be regretted for their own sake; but still more so for the sake of those who may come under their educational influence. It is not to be expected that men who have never been compelled either to study elementary geometry intelligently, or to give more proof of their knowledge than is involved in the mechanical 'writing out' of propositions from memory should develop into good teachers of the subject. As they have learnt so will they teach—without interest and without intelligence." I used the words "consist *almost* always of book work;" a little while since the qualification might have been omitted, but there does occur a strange, almost portentous, innovation in the last Trinity Term "Smalls" Euclid Paper. At the end of the Paper, tacked on to I. 12, occurs the question, "*Why must the given straight line be of unlimited length?*" This really looks like a rift in the clouds; we may hope for brighter days; "c'est toujours avancer, que de faire un pas, quoiqu'il ne soit pas grand."

I conclude with a cordial invitation to those interested in our work to attend our afternoon meeting at University Colllege, to-morrow (January 16th) at 2 p.m.—Yours truly,

EDWARD M. LANGLEY, Hon. Sec., A.I.G.T.

16, Adelaide-square, Bedford.

"WHAT IS ELECTRICITY?"

TO THE EDITOR OF THE ELECTRICIAN.

SIR: That much-debated and apparently unanswerable question, "What is electricity?" having been once more raised in your columns, will you kindly allow me to draw attention to one or two points affecting this question?

You have already very ably replied to Dr. Molloy's letter in your issue of the 1st inst., and it must be evident to all that a comparison of work done by heat in falling from a higher to a lower temperature with water in falling from a higher to a lower level, and electricity in falling from a higher to a lower potential, which draws a distinction between the first and the two latter cases, on the ground that in the case of heat the work done is equivalent to the heat which has *disappeared*, whereas in the cases of the falling water and electric "current" there is no disappearance of water or electricity—is essentially wrong. In neither case is there a disappearance of anything—merely a transfer of motion.

But "What is an electric current?" is the question so often asked, and as often has the attempt been made to give a satisfactory explanation. We have had the older theory representing the electric current as conveyed *through* the conductor with its hydraulic analogue, and the modern view of the ether as the medium through which the transfer takes place, both ably championed, yet with no more apparent result than that of showing more clearly the weak points of both.

There is one point which seems to be much overlooked by both parties, viz., that the electrical transmission of energy *is a function of the ultimate particles of matter.*

That the electrical transmission of energy is in some way dependent upon the molecular constitution of the solid "conductor" is indisputable. Yet upholders of the modern views appear to argue their case of the ether as the active agent in such cases of energy transfer, quite regardless of the constitution of the solid "conductor." In fact, to all appearances, a rod of glass would suit their purpose as well as a rod of copper.

Those holding the older views and suppose an actual flow of something to take place in the conductor, or a propagation of energy by an end thrust or its equivalent, also seem to give little thought to the ultimate constitution of the conductor, and show no reason why such a flow should not take place equally well in the best insulator and the best conductor.

The mere assertion that the one is a conductor and the other an insulator seems to serve without further attempt at explanation.

We have no knowledge of electricity apart from matter; and this, to me, plainly indicates that it is to matter that we must look for a satisfactory explanation of the electric "current."—Yours, &c.,

WALLACE H. PAULL.

Handsworth, January 12, 1892.

STEAM-ENGINE ECONOMY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is said by one of your contemporaries in last week's issue that, in a report to the Portsmouth Town Council, Professor Garnett has stated that the Parsons turbo-generator is now "as efficient as the best compound engine of the marine type, and that for light loads it stands unequalled." The authority for these statements is said to be the report by Professor Ewing, F.R.S., published in your paper for last week.

Those interested in the "best compound engines of the marine type" (as electric light engines) will no doubt take care of their own credit; but the Continental users of direct-coupled condensing engines of this pattern will perhaps be surprised to hear that a plant which uses 27·6lb. of water per electrical H.P. per hour when working condensing is formally stated, in a report by the electrical expert of one of the most important English towns, to be as efficient as their own.

Our concern is with the statement that "for light loads it (the turbo-generator) stands unequalled." We beg to assure Prof. Garnett that there are no figures in Prof. Ewing's report which bear this out. At low temperatures the turbo-generator is, for obvious reasons, *relatively* a more efficient machine than an expansive steam-engine; but at no power quoted (not even at *no* electrical load—at which even an alternating station can hardly want to run) is the consumption nearly so low as that in the best Willans engines with direct-driven dynamos—of course, when working condensing. At full load the consumption of the turbo-generator reaches, as above stated, to 27·6lb. per E.H.P. hour, a figure usually surpassed by the Willans *non*-condensing engine. In many recent trials of a Willans condensing engine (of much smaller power than the turbo-generator tried at Newcastle; in fact, indicating only from 30 to 40 H.P.) the consumption per I.H.P. per hour has been about 12·8lb. of steam. With a combined efficiency of 80 per cent., which is the lowest we are accustomed to get with good dynamos, this corresponds with 16lb. per electrical H.P. per hour.

These figures, which are recent, are probably not known to Prof. Garnett; but Prof. Ewing's report speaks of published trials with a Willans engine, in which the consumption was about 25lb. per unit, or, say, 18·6lb. per electrical H.P. Yet Prof. Garnett totally ignores these figures from an actual engine (compared with which those of the turbo-generator are *about half as large again*, and makes comparison with nothing but an engine of a kind which no one in this country would be likely to use; whereas the Willans engine is used in England (for central stations) to the extent, probably, of 2 H.P. for every 1 H.P. of all other kinds of engines put together. Thus, in the comparative estimates stated to have been drawn up for the guidance of the town councillors, the cost of an installation of turbo-generators is compared with that—not of Willans engines, or of any other form of direct-driven plant—but with an absurdly obsolete plant consisting of engines "making not more than 90 revolutions per minute, coupled by endless rope-gearing to dynamos, making 300 revolutions per minute.—Yours, &c.,

WILLANS AND ROBINSON (Limited).

C. S. ESSEX, Secretary.

THE CUTTRISS TELEPHONE.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Referring to the description of the new Cuttriss telephone that you published in your issue for last week, the following extract from Prescott's Book on the Telephone, 1879 edition, page 545, is instructive:—

Digitized by Google

"*Short-Circuiting Telephones.*—A spiral spring is wrapped round a cylinder, the diaphragm pressing against the last turn, so that in vibrating the convolutions approach or recede from one another. A very slight motion of the diaphragm is sufficient to cause the first few coils to come together; and in general the number of coils that thus touch each other is dependant upon the amplitude of the diaphragm's motion. The wire is included in the primary circuit of an induction coil, so that the resistance of the circuit fluctuates as the diaphragm vibrates."

It is difficult to see any great difference between the telephone thus described in 1879 and Mr. Cuttriss's new instrument. The composition of the spiral is, indeed, not indicated; but at the date mentioned it was already well known that carbon was the best material for all microphonic purposes.—Yours, &c.,

A. A. C. SWINTON.

66, Victoria-street, London, S.W., January 11, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Offices not later than first post Thursday morning.*]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—The Durban (Natal) Town Council is prepared to grant concessionary rights to an undertaker for the establishment of electrical conductors for the supply of electricity to the town of Durban. Some particulars will be found in our advertisement columns; and printed conditions, with plans of the town, may be obtained on application to Mr. W. H. Radford, C.E., consulting and representative engineer to the Durban Corporation, Angel-row, Nottingham, England. Tenders must reach the Town Clerk, Durban, Natal, on or before April 30, 1892.

SALE BY TENDER.—We have received from Messrs. Wheatley Kirk, Price, and Goulty, the schedule and plans of the pumping engines and boilers which they are instructed by the proprietors of the East London Waterworks Company to sell by tender. The engines may be seen at work on any week-day by arrangement with the auctioneers. The engines and boilers for disposal are of the "Hercules," "Cornish," "Ajax," and "Wicksteed" types, and are erected upon the late premises of the Waterworks Company at Old Ford-road, Bow, London, E.

ALMANACKS, &c.—We have received from the Bell's Asbestos Company a neatly-printed illustrated sheet almanack.

——— We have received from the Anglo-American Telegraph Company a blotting pad and calendar for 1892, upon which is printed a section of a map showing the cables owned by the Company.

ROPER'S ELECTRICAL ENGINEERING COMPANY (LIMITED).—This firm sends us a copy of their newly-issued catalogue.

THE PAST YEAR'S WORK.—Messrs. J. D. F. Andrews and Co. report that their system of concentric wiring has come into general favour during the past year. Many important installations have been carried out both in London and the country, including a large installation at the Waterloo Grain Warehouses and the Park Hill Petroleum Stores. Three contracts have been concluded with the Mersey Dock Board. It will be in the recollection of our readers that a number of the leading insurance companies have had this system under their consideration during the past year, and have included clauses in their rules dealing with its introduction. Messrs. Andrews and Co. have also during the part year executed some large ventilating contracts.

——— Messrs. W. T. Goolden and Co. report favourably of the past year's work, all branches of their extensive business having experienced considerable activity. The firm have executed large contracts for dynamos, instruments, and accessories for central station work, and for private house and other installation work by steam and water power. The electric mining machinery department has been exceptionally active, and the contracts for the year include plants for pumping, holing, rock drilling and coal cutting. The supply of motors for workshops, launches, &c., has also been considerable during the past year. The prospects for the present year are reported fairly good.

——— The Telegraph Manufacturing Company have again to report progress and full work in all their departments. During the past year a largely-increased sale has taken place in their well-known manufactures of vulcanised and other cables for electric lighting. In telephone switchboards, railway telegraph, and other instruments, a heavy year's work has been done; their new Liverpool instrument workshop having been kept fully going. Nearly a quarter of a million Leclanché batteries have been made and sold during the past twelve months, and the demand for insulators and line stores has been very large. This is no doubt partly due to the expiry of the telephone patents, but at the same time is also largely due to the promptness with which this Company execute the large orders entrusted to them. It will be remembered that about eight years back the Company commenced the manufacture of gutta-percha wire and cable, and large orders have been received during the past year for these manufactures. For 1892 the Company starts with the brightest prospects for a busy year's work.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

COMPANIES' MEETINGS & REPORTS.

Eastern Telegraph Company (Limited).

The thirty ninth half-yearly ordinary general meeting of this Company was held yesterday, at Winchester House, Old Broad-street, under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. George Draper) having read the notice convening the meeting,

The CHAIRMAN, at the outset of his remarks, referred with the deepest regret to the death of the Duke of Clarence, and expressed his conviction that they would all cordially sympathise with the Royal Family in the great trouble which had fallen upon them. Probably on no other occasion had news passed so rapidly over this vast Empire as the news of the death of his Royal Highness. The Company in which those present were all so much interested had been the medium of conveying the sad information to almost every civilised portion of the world, which had thus been made acquainted with it almost within the same space of time as we had been in London. He was convinced that throughout the world the deepest sympathy would be expressed with the Queen and the Royal Family. Referring to the working of the Company in the half-year to September 30th last, he stated that their message receipts for that period had been £321,135, being an increase of £2,407 over those of the corresponding period of 1890. The dividends from their investments in other companies had been £33,399, or £56 less. Their gross revenue had been £354,939, or an increase of £2,066. They would remember that from July 1st a considerable reduction of rates came into operation on inter-European telegrams ; and he was glad to say that this reduction had now been nearly recouped, showing the considerable vitality which existed in their business. Included in their present accounts was the loss on five months' traffic occasioned by the reduction of the tariff to Australia. They had had about eight months' experience of this reduction, but when he met them next time he thought he would be able to make a very satisfactory announcement on the subject. He did not think it desirable to give any figures at that moment; but it must be satisfactory to the shareholders to know that in spite of the important reductions in the tariff between European countries and with Australia, increased traffic with other countries where they had not been obliged to reduce their tariff – notably with South America—had enabled them, not only to cover the loss resulting from the reductions, but to show a small increase of revenue. The total expenses for the half-year had been £97,130, or £5,407 in excess of those of the corresponding period of the previous year. Included in this half-year's figures, however, was the item for "special repairs to buildings at Alexandria and Port Said, £2,450;" and the amount carried to the "maintenance ships' reserve fund" was £4,000, against only £2,500 in the corresponding period of the previous year. Several of the other items showed an increase, while in others there was a decrease. The general expenses in London had been £9,412, or £910 more. The working expenses at stations had amounted to £73,097, showing an increase of £4,662. The additional expenditure under the heading of salaries, wages, rent, &c., was incurred last year, the necessary increase in the number and additional pay and allowance granted to some of the foreign staff being the cause. The use of patents had cost them £755, against £1,416 in the September half of 1890. The reduction now shown would be permanent, some of the patents for which they had been paying royalties for several years having expired. The expenses attending repairs and renewals of cables had amounted to £47,048, showing an increase of £15,570. In the corresponding period of 1890 the amount chargeable for repairs for cables was exceptionally light, owing to the large credits derived from other companies for the hire of the Eastern Company's ships for cable repairing purposes. They had laid in 129 knots of new cable, the cost of which was included in the half-year's figures. The result, therefore, of this half-year's working was that, although they had a small increase in their gross revenue, they carried forward £57,509, against £78,195 in the corresponding period of 1890, or a decrease of £20,686. It must, however, be remembered that the September half of 1890 was an exceptionally favourable one as regarded ships' expenditure. He desired to call their attention to the important fact that, in spite of the large additions which they had made to their cable system during the last six years, the capital expenditure under this head had remained since 1885 at practically the same figure, notwithstanding that they had laid over 7,000 miles of new cable during that period. This half-year they had applied from the reserve fund the sum of £105,110 in reduction of capital expenditure, and the total amount charged against reserve and revenue accounts to September last was £1,101,463. The balance remaining in their general and other reserve funds was £508,509. He thought they would consider this a very satisfactory position to be in. About eleven years ago the shareholders were good enough to sanction the establishment of a staff endowment assurance fund. A few months ago, when he was addressing the Eastern Extension Company he drew the attention of the shareholders to an amended system which the Directors desired to introduce, and which at the present time was in the hands of the actuaries. Telegraphing was a very peculiar business. Probably the young men they employed were, so far as their fingers were concerned, more expert and cleverer than when they attained to double their age. If they were to get good servants around them they must hold out the prospect of some benefit for their enjoyment at the end of a long and arduous life. They thought that by encouraging thrift and economy and wise forethought on the part of their *employés*, they could attain the object in view by adding, on the part of the Company, to the sum created by the *employés*, so as to enable the latter to retire with a competency after attaining the age of fifty or sixty, as might be determined upon. The shareholders must bear in mind that their business was not an ordinary one, but one which necessitated great confidence being reposed in their servants ; and it was necessary for them to have around them a class of men rather above the average—men in whom confidence could be placed, well educated well connected, and men, in short, who would have some respect for their names and the position held by them. The shareholders must bear in mind that a great deal of their work was conducted in distant countries, in tropical climates, and not in very pleasant places. Living in these places did not tend very much to health, but still the Company always found men ready and willing to serve them; but they felt that it was very desirable to be just and generous to their *employés*, and to let them feel that the Company were in touch with them. As he had said, he would not go into the details of the scheme on that occasion, the matter being before actuaries, but he was very glad to witness the signs of approval which the shareholders had given to his remarks relative to what was intended. As he had said before, telegraphing became a greater necessity every day, and as the world grew, so must the demand for telegraphy increase ; and their arrangements and appliances placed them at the head of everything connected with telegraphy. They had some cables still to duplicate, and this work would be carried out in due course. They were, however, most desirous, above all things, not to overburden their capital. Taking into consideration the reduced value of money he thought it was very gratifying that they were still able to maintain their dividend. He thought they might be satisfied that the investment they had made in the Company was a good and sound one, and it was regarded in that light by the commercial world ; for, in spite of the great depression which had prevailed for so long, the shares of the Eastern and of the Eastern Extension Companies stood rather higher to-day than at any period of their existence ; while their Four per Cent. Debentures were quoted at 108 to 109. He concluded by moving "That the report and accounts of the Directors to September 30, 1891, submitted to this meeting be and the same are hereby received and adopted."

The VICE-CHAIRMAN (the Most Hon. the Marquis of Tweeddale) seconded the motion.

A brief discussion followed, in which Mr. JOHN NEWTON, Mr. WEIR, Dr. WALLER, and Mr. WHISH took part.

The CHAIRMAN, in reply, stated that in the pension scheme to which he had alluded the shareholders might rely that the old and faithful servants of the Company would certainly not be forgotten. He had been asked whether their cables were in working order ; and he might state that they were in a condition above the average. They were rarely without a broken cable, but having adopted the system of duplicate cables wherever they had been able to do so, the public knew very little about breaks when they occurred. He might state that they had a very important break the other day in the South African cable, which, though another Company's, was practically owned by this Company. Had they not had their ships in order to attend to this break at once, the delay in

Digitized by Google

effecting the repair would have been considerable. It was a remarkable fact that this cable was broken and repaired within five days, whereas if the matter had not been under their own control the repair would probably have taken two months. They not only repaired their own cables but some for other people besides. They never allowed their ships to lie idle if they could help it. During the present half-year they earned outside their own Company by their ships £15,000 ; and in the corresponding half-year of 1890 they earned in a similar way £22,000. He then put the resolution, which was carried unanimously.

On the motion of the CHAIRMAN, seconded by the MANAGING DIRECTOR (Sir James Anderson). Sir A. J. Leppoc Cappel, K.C.I.E., was re-elected a Director ; as was also Lord Sackville A. Cecil, on the motion of the CHAIRMAN, seconded by Mr. J. D. PENDER.

The auditors (Mr. Henry Dever and Messrs. Welton, Jones and Co.) were afterwards re-elected.

Mr. NEWTON then proposed, and Dr. WALLER seconded a vote of thanks to the Chairman and Directors, both speakers cordially testifying to the services rendered by these gentlemen.

The CHAIRMAN, in reply, observed that there was no encouragement so great and so stimulating as that of the approval, six months after six months, of the body of their shareholders in the work done for them by their Directors. He was going away for a couple of months, and he intended to visit some of the Company's stations in the Levant and other places. He would thus be brought into contact again with their *employés* abroad ; and the shareholders would be astonished to see how extremely thankful their servants were on the occasion of such visits. He was convinced that the more they could keep in touch with their people the better would they get their work done.

The proceedings then terminated.

(A full report of this meeting will appear in our next issue.)

Edinburgh Electric Supply Corporation (Limited.)

The second annual general meeting of the shareholders of this Corporation was recently held in Edinburgh Mr. Walter Berry, of Glenstriven, chairman, presiding.

The Directors' report made reference to the negotiations entered into with the Town Council, setting forth the position of the Company and the advantages that would result to the city were an arrangement arrived at whereby the lighting of the compulsory area comprised in the Provisional Order should be undertaken by it. The subject, the report continued, must shortly be considered by the Councillors, as they obtained the Royal assent to their Provisional Order in the beginning of last July, from which date they had only three years to complete this work within the compulsory area. Meantime, the Directors had collected a large mass of information and statistics connected with similar works, finished and in progress, throughout the United Kingdom and elsewhere, which would enable them to tender for the electric lighting of the city should the Town Council decide on delegating their powers to the Company. In the meantime the shareholders had incurred no liability with regard to the expenses, nor would they do so unless the desired contract was obtained from the Council, when the shares would be issued to the public, and the business of the Corporation be at once proceeded with.

The CHAIRMAN, in moving the adoption of the report, said he had to express the regret the Directors felt in being still unable to intimate any progress towards the definite fulfilment of the object for which the Company was formed ; but no one was to blame for that. Without being too pressing, the Directors had not failed to urge their claims on the Town Council, and he could not doubt that these would be favourably considered when the Council was in a position to come to a decision. They must, of course, recognise that their representatives in the Council might decide that in the public interest it would be preferable for them to undertake the work themselves, and he had no doubt that, should they so decide, their decision would be arrived at on sufficient grounds. In that case the existence of their Corporation would terminate, and the preliminary subscriptions of the shareholders would be returned in full. As they were aware, the reasons why this Company was originally formed were—first, that it was deemed that there was sufficient business capacity in Edinburgh to carry out the electric lighting of our city, and that there was sufficient public spirit to form a local Company for that object ; secondly, that they objected very strongly to be tied to any one system. They knew that the Company against which they appeared as competitors was limited to its own special method, against which he had not one word to say. It might still prove the best, but they thought it well worth the trouble involved to attempt to keep our city free to adopt the best obtainable. Therefore, if the city entrusted the electric lighting of Edinburgh to their Company they should do their best to keep in the front rank, both scientifically and practically. They were naturally anxious to have the business ; but the shareholders might rest assured that although their Directors would not be greedy for profit, they would not undertake any contract which did not, in their view, leave a good margin for interest and risk.

Mr. G. BARCLAY having seconded the motion for the adoption of the report, it was adopted unanimously ; and, on the motion of Sir THOMAS CLARK, a vote of thanks was passed to the Chairman.

British Electric Light Company (Limited).

The ordinary annual general meeting of the shareholders of this Company was held on December 30, 1891, at Westminster. The proceedings were merely formal, and no business was done beyond the adoption of the Directors' report and accounts, and the re-election of Mr. W. F. Williams, the retiring Director, and of the auditors.

The following is the Directors' report read and adopted at the meeting :—

"The Directors beg to submit to the shareholders the accounts and balance sheet, showing the working of the Company for the past year, ending October 31st.

"In consequence of the Woodhouse and Rawson Manufacturing and the Woodhouse and Rawson Supply Company having gone into liquidation, the business carried on under the agreements with those Companies ceased, and the terms of a settlement of all outstanding claims have been arrived at, and are now waiting completion. A new arrangement was then entered into with the Ateliers Hoster de St. Nicolas (Limited), and with the Electric Stores (Limited) for the manufacture and sale of lamps, Mr. Albert Hoster acting for both companies. Under this arrangement the benefit to this Company from the sale of lamps will extend for ten years beyond the term of Messrs. Edison's patents. An agreement has also been come to by which this Company will, during the term of Messrs. Edison's patents, not manufacture any incandescent lamps, this Company receiving £2,000 compensation. Included in this arrangement is the settling up of all and every outstanding differences between the Woodhouse and Rawson Companies, Edison Swan Company, and this Company, leaving it in future a free hand to carry on its own business without the constant risks and expenses of legal proceedings, which have been so frequently threatened and incurred during the last two years. The Company will immediately benefit by this arrangement, and steps have already been taken to start other business.

"A reference to the account will show a balance to the credit of profit and loss account of £1,286. 13s. 10d , which is inclusive of £427. 11s. 8d. brought forward after payment of dividend last year. This amount is in part made up of certain sums still outstanding in the claim against Messrs. Woodhouse and Rawson.

"Of the available balance the Directors propose to pay interest at the rate of 5 per cent. on the Ten per Cent. Preference Shares, and 3 per cent. on the Six per Cent. Preference Shares, which will require £648. 10s., leaving the balance to be carried forward.

"Mr. W. F. Williams, the Director retiring by rotation, and Messrs. James and Edwards, the retiring auditors, being eligible, offer themselves for re-election."

NEW COMPANIES, STATUTORY RETURNS, &c.

ELECTRIC FITTINGS, HIRING, AND MAINTENANCE COMPANY (LIMITED).—This Company was registered on January 6, 1892, with a capital of £200,500, divided into 40,000 ordinary shares of £5 each and 500 founders' shares of £1 each, by Messrs. Ashurst, Morris, Crisp, and Co., 17, Throgmorton-avenue, London, E.C. The objects are :—(A) to construct, lay down, establish, fix and maintain all cables, wires, lines, accumulators, lamps, works, and fittings of every description for the generation, distribution, supply, accumulation, and employment of electricity. (B) to carry on the business of electricians, generators, and suppliers of electricity, mechanical engineers, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, distribution, and employment of electricity. (C) to carry on all or any of the businesses of iron, brass, metal, and other founders and fitters and metal workers, and for other purposes. The first subscribers are :—

	Shares.
Sir A. Armstrong, K.C.B., The Albany, Piccadilly	1
Colonel B. H. Martindale, C.B., Bickley, Kent	1
William Crookes, F.R.S., 7, Kensington Park Gardens, W.	1
F. R. Reeves, Little Heath, Potters Bar, electrical engineer	1
Arthur Palliser, jun., 21, Lime-street, E.C., merchant	1
Harry Fleet, 4, Heyworth-road, Clapton, London, accountant	1
Joseph William Tucker, 14, Addiscombe-grove, Croydon	1

The number of the Directors is not to be less than three nor more than seven. The first Directors shall be the persons who shall be nominated by a majority of the subscribers to the Memorandum of Association. Qualification, the holding of shares of the Company of the nominal value of £200.

INVENTIONS CONTRACT SYNDICATE (LIMITED).—This Company was registered on January 7, 1892, with a capital of £5,000, in £1 shares, by Emanuel, Round, and Nathan, 27, Walbrook, London, E.C. The objects are "to establish, acquire, and carry on all or any of the businesses of manufacturers, vendors, and purchasers of and dealers in all inventions, patents, and processes incidental to the business of engineers, and also manufacturers, producers, vendors, and purchasers of and dealers in all mechanical and engineering machines, inventions, contrivances, and processes, pneumatic, hydraulic, chemical, and electrical apparatus, machines, and inventions, and metallurgical processes of any nature and for any purpose whatever."

MEIN'S ENGINE COMPANY (LIMITED).—This Company was registered on January 5, 1892, with a capital of £3,500, in £1 shares, by Le Brasseur and Oakley, 12, New Court, Lincoln's Inn. The objects are to work tramways, omnibus, railway, subway, and other lines, by mechanical and other power, to generate and sell power for locomotives, fixed engines, or any other purposes, and to form centres for the accumulation and distribution thereof. The first subscriber is Mr. Edward Mein, Station-street, Stratford, London, E., engineer.

METROPOLITAN LIGHT COMPANY (LIMITED).—This Company was registered on January 7, 1892, with a capital of £5,000, in £1 shares, by John Hands, 15, Old Jewry-chambers, London, E.C. The objects are : To

Digitized by Google

purchase or otherwise acquire the business now carried on by Daniel C. Defries at 43 and 44, Holborn-viaduct, London, under the name of "The Metropolitan Light Company;" to carry on the business of manufacturing or mechanical engineers, gas engineers, electrical engineers, machinists, ironmongers, &c., and to provide and supply gas or electricity, or electrical currents or force for lighting and heating purposes. Mr. Daniel C. Defries is the Managing Director until he resigns the office, or dies, or ceases to hold at least £1,000 in shares.

OAKDEN AND SHARPE (LIMITED).—This Company was registered on January 9, 1892, with a capital of £20,000, divided into 15,000 ordinary shares of £1 each and 500 preference shares of £10 each, by Waterlow and Sons (Limited), London Wall, E.C. The objects are to acquire and carry on the business (amongst others) of wholesale and general furnishing ironmongers, steam, electrical, and ventilating engineers, electricians, and art metal workers, carried on by Messrs. Oakden and Sharpe, at Great Grimsby, Lincolnshire.

BRITISH ELECTRO-CHEMICAL AGENCY (LIMITED).—The statutory return of the above-named Company made up to the 24th December, 1891, was filed on the 6th January, 1892. The Company was registered on the 11th August, 1891, with a capital of £75,000, divided into 5,000 ordinary, and 2,500 "vendors'" shares of £10 each, to acquite certain patents from the Electric Construction Corporation (Limited), and to work the same. The directorate comprised Mr. Joseph Ebbsmith, Mr. John B. Verity, and Mr. James Balfour. At the time of making-up, 4,099 shares were taken up, and upon 1,599 ordinary shares £1 per share had been called, resulting in the payment of £839. 10s., leaving £759. 10s. in arrears. Registered office: Worcester House, Walbrook, London, E.C.

CENTRAL ELECTRICAL COMPANY (LIMITED).—The first registered office of the above-named Company (full particulars of which were published in *The Electrician* of last week) is situate at 47 and 48, Broad-street-avenue, London, E.C. (filed on January 5, 1891).

CHATHAM, ROCHESTER, AND DISTRICT ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to December 23, 1891, was filed on January 4, 1892. The Company was registered on July 15, 1887, with a capital of £10,000, in £5 shares. By special resolution, passed November 21, 1888, and confirmed December 13, 1888, the capital was raised to £50,000 by the addition of 8,000 shares of £5 each. 2,027 shares have been taken up, upon 2,000 of which the full amount has been called, and upon the remaining 27 £1 per share has been called, resulting in the payment of £10,025, and leaving £2 unpaid. Offices and works: Victualling Office Wharf, Rochester.

CRYSTAL PALACE DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The approval of the Board of Trade to the change of the above Company's name from the Electric Installation and Maintenance Company (Limited) to its present title, was granted on January 1, 1892, and the official certificate granted on January 4, 1892. Registered office: 4, Great Winchester-street, London, E.C.

ELECTRICITY SUPPLY CORPORATION (LIMITED).—At an extraordinary general meeting of the members of the said Company, duly convened and held at No 2, Craig's-court, Charing-cross, in the County of London, on December 7, 1891, the following special resolution was duly passed; and at a subsequent extraordinary general meeting of the said Company, also duly convened and held at the same place on December 22, 1891, was duly confirmed:—"Resolved unanimously that the capital of the Corporation be increased from £100,000 to £150,000, and that such further sum of £50,000 consist of 5,000 ordinary shares of £10 each, to rank equally with the ordinary shares of the Corporation in all respects." The annual return of the above-named Corporation, made up to January 5, 1892, was filed on the same day with the above. The Company was registered on June 12, 1889, with a capital of £100,000, divided into 9,900 ordinary and 100 founders' shares of £10 each, to apply for, obtain, undertake, and carry out a Provisional Order for the supply of electric light and power within the parish of St. Martin's-in-the-Fields, in the county of Middlesex, and also generally any contracts, Acts, Provisional Orders, licences, decrees, and concessions for or in relation to the supply of electricity in Great Britain and elsewhere. At the time of making-up, 359 ordinary shares had been taken up, the full amount called, and all calls paid. Registered office: 12, Maiden-lane, Covent-garden, London, W.C.

GENERAL ELECTRIC POWER AND TRACTION COMPANY (LIMITED).—The first annual return of the above-named Company, made up to January 1, 1892, was filed on the 9th following. The Company was registered on May 22, 1890, with a capital of £350,000, divided into 10,000 preference and 25,000 ordinary shares of £10 each, to unite the businesses of the Electric Traction Company (Limited) and Moritz, Immisch, and Company. At the time of making-up, all the preference and 23,592 of the ordinary shares had been taken up, and 21,734 ordinary shares were issued and considered as fully paid. Upon the preference shares £6 per share has been called, and upon the remaining 1858 ordinary shares the full amount has been called. The total amount of calls received, including payments on application and allotment, is £59,085 on the preference shares and £17,950 on the ordinary shares, leaving £915 due on the preference and £630 on the ordinary shares. Registered office: New Broad Street House, London, E.C.

NATIONAL COMPANY FOR THE DISTRIBUTION OF ELECTRICITY BY SECONDARY GENERATORS (LIMITED).—The annual return of this Company made up to December 30, 1891, was filed on January 6, 1892. The Company was registered on May 11, 1883, with a capital of £500,000, in £10 shares, which shares are now divided into 3,000 preferred and 47,000 ordinary.. 2,669 preferred and 20,000 ordinary shares have been taken up, and upon 1,669 of the preference the full amount has been called and paid. The total amount of calls received, including payments on application and allotment and £1,000 paid on forfeited shares, equals £17 690. Total amount agreed to be considered as paid on 1,000 preferred and 20,000 ordinary shares is £210,000. Registered office: 18, Warwick-street, Regent-street, London, W.

NATIONAL ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of this Company, made up to the 13th May, 1891, was filed on the 7th January, 1892. The Company was registered on the 28th October, 1889, with a capital of £100,000, divided into 19,900 ordinary and 100 founders' shares of £5 each. At the time of making-up, 98 founders' and 490 ordinary shares had been taken up, and upon the founders' shares £5 per share had been called, while upon the 490 ordinary shares £1 per share has been called, the whole resulting in the payment of £2,875, leaving £65 unpaid. Registered office: Victoria-buildings, Preston.

NEW CADOGAN AND BELGRAVE ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 1, 1892, was filed on January 7th. The Company was registered on June 30, 1890, with a capital of £1,000, in £10 shares, to acquire, take over, and carry on the business of the Cadogan Electric Light Company (Limited). At the time of making-up, seven shares had been taken up, upon which, however, nothing had been called or paid, the original subscribers being the only shareholders. No agreements for the taking over of any business, plant, contracts, &c., have as yet been filed. Registered office: 91, Manor-street, Chelsea, London, S.W.

OXFORD ELECTRIC COMPANY (LIMITED).—The statutory return of the above-named Company, made up to the 26th December, 1891, was filed on the 9th January, 1892. The Company was registered on the 24th of August, 1891, with a nominal capital of £100,000 in £5 shares, to carry on in the City of Oxford and its neighbourhood the business of electric lighting in all its branches, and to enter into and carry into effect an agreement about to be made with the Electric Construction Corporation (Limited). At the time of making up, 67 £5 shares had been taken up, £2. 10s. called on each, and £100 paid, leaving £67. 10s. in arrears. A note at the end of the return states that "In addition to the above shares 10,100 shares are appropriated for payment on completion of the works in progress, under contract August 13, 1891, made between this Company and the Electric Construction Corporation (Limited), Worcester House, Walbrook, E.C.—(Signed), GEORGE OFFOR, Manager and Secretary." Registered office: 4, Great Winchester-street, London, E.C.

ST. PAUL'S PRINTING AND PUBLISHING COMPANY (LIMITED).—The first registered office of the above Company (*see* last week's *Electrician*) is 22, Paternoster-row, London, E.C.

TELEGRAPH IMPROVEMENT COMPANY (LIMITED). — The annual return of the above-named Company, made up to December 29, 1891, was filed on January 7, 1892. The Company was registered on June 8, 1881, with a capital of £100.000 in £1 shares, to acquire and work letters patent dated February 12, 1875, No. 525, granted to George Allan and James Wallace Brown, for the invention of "Improvements in Electric Telegraphs," and letters patent, dated April 26, 1876, No. 1,757, also granted to G. Allan and J. W. Brown, for an invention of "Improvements in Electric Telegraphs." At the time of making up, 15,006 shares had been taken up, upon 6 of which the full amount had been called and paid, the remaining 15,000 having been issued as fully-paid. Registered office: 10, Austin-friars, London, E.C.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended January 10th amounted to £858, as against £748 for the corresponding period of 1891, an increase of £110.

ELECTRICAL FITTINGS, HIRING, AND MAINTENANCE COMPANY (LIMITED).—We have received a copy of the prospectus of this Company, which is formed with a capital of £200,500, in 40,000 ordinary shares of £5 each, and 500 founders' shares of £1 each, the whole of the latter having been subscribed for. The present issue is for £100,000, in 20,000 ordinary shares of £5 each, payable 10s. per share on application, £1 per share on allotment, and the balance in sums of £1 at intervals of not less than two months. The Directors are Sir Alexander Armstrong, K.C.B.; Colonel B. H. Martindale, C.B.; Prof. W. Crookes, F.R.S.; and Messrs. J. Browne-Martin and T. G. Fardell; and the secretary and offices (*pro tem.*) are Mr. W. F. L. Frith, 9, Austin Friars, London, E.C. The prospectus states that the Company is formed for the purpose of assisting intending consumers of the electric light in adapting the same to their establishments. The Company propose to facilitate the introduction of electric light and power by executing all the needful interior work of buildings, &c., and receiving payment for this work by instalments. The Company will be prepared to supply all kinds of lamps, electroliers, motors, &c., and for this purpose will establish show rooms, where samples of apparatus and fittings will be on view. The Company will issue a guarantee with all its work, and maintain the same free of cost for the sum agreed upon between the parties. Prospectuses and forms of application for shares can be obtained of the bankers of the Company, Messrs. Barclay, Ransom and Co.; of the solicitors, Messrs. Ashurst, Morris, Crisp and Co.; or at the offices of the Company.

GLOBE TELEGRAPH AND TRUST COMPANY (LIMITED).—At a meeting of the Directors, held on Tuesday, an interim dividend was declared of 3s. per share on the preference shares, less income-tax, and of 1s. 6d. on the ordinary shares, income-tax having already been deducted.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 714.—Vol. XXVIII. FRIDAY, JANUARY 22, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The Memorial to the Board of Trade on the subject of overhead wires has received a very large number of signatures, thus showing, as Major Flood Page observes in his letter, which will be found elsewhere, that there was a general feeling of anxiety that all overhead wires would be disallowed. The letter, which was sent to Messrs. Crompton and Co. was certainly sufficient to warrant the steps which were taken to draw up a Memorial and to make preliminary arrangements for an influential deputation; but we hope that by the publication of the other letter of the Board of Trade in our issue of the 8th inst. we have saved the President of that Department from some trouble, by making such a deputation unnecessary. We take it that the letter addressed to Messrs. Crompton and Co. related specifically to the lighting of Chelmsford, though by omission to make this clear it seemed to lay down a general rule.

We are not aware that any publication has yet been made of the "cases" in which overhead wires shall be or shall not be employed. It is possible that the pushing of the Memorial and of the proposed deputation might elicit some explanation; but it seems much more discreet to await further action by the Board of Trade, and not to force any premature decision. It is very evident to all who have had dealings with the Electrical Department that there is every desire on the part of the few but well-intentioned officers to do the best they can both for individuals and for the industry; and it is not advisable to encourage so slender a staff to make hasty decisions on matters of considerable weight. If any hard and fast rule is made now, it will practically have to be made by one or two men who have their hands full of other Government business.

Although, as Major Flood Page points out, the statement "that they will be prepared to authorise the use of such wires in any case in which they are satisfied that the interest of the public require it" cannot be regarded as altogether a satisfactory position in which to leave the question, we are given to understand that the intention of the Board of Trade is simply to disallow overhead wires in towns, and to permit them in the country. The question will resolve itself eventually into a definition of "town" and "country;" and the knotty point is, that what is country to-day may be town to-morrow. The street lighting of Chelmsford is obviously a case of "town"; the road between Weybridge Station and the town is probably a case of "country."

There exists at present, we understand, a statutory definition of a "rural sanitary district." We know nothing of, and take no interest in, the matter, except that any district which is recognised by Act of Parliament as "rural," will in all probability be allowed to add overhead wires to its natural charms. Another and supplementary definition, "urban sanitary district," includes, we imagine the remainder of the British Isles, and with it unhappy Chelmsford. But the Public Health Act, we are informed, deals with this question, and if a definition is introduced, the present condition of uncertainty is then at an end.

The financial results of last year's working of the St. James' station, which are set forth at some length in another part of the present issue, are of the satisfactory character to be anticipated in the case of a central station so favourably situated and so judiciously managed. In return for a total capital outlay of £139,000, the shareholders are in a position to place some £10,000 or more in their pockets, with the additional comfort of knowing that the money has been genuinely earned, that there is a reserve of £15,000, and that a "redemption fund" has been founded, The current metered during 1891 brought in £31,000 in round figures, which, taking the B.T.U. at 7d., means that considerably more than a million units were sold. The expenses of generation and distribution came to £11,187, or about 2½d. per unit; if we include expenses of management, depreciation, &c., we have roughly to double this figure; so that each unit metered must have brought in a clear profit of about 2d.

We print this week an interesting contribution by Dr. Fleming to the subject of alternate-current curves. The curves, already published by Messrs. Ryan and Merritt, have been subjected by them to a most searching analysis. The whole article is of interest, but that portion of it which deals with the magnetic leakage of transformers is of special value. The theory of transformers has, during the last two or three years, been simplified, and, at the same time, rendered more accurate, by the disuse of coefficients of self and mutual induction to represent the magnetic action of the coils, and by the adoption, in preference, of Dr. Hopkinson's

Digitized by Google

method, in which only the total number of lines of force passing through the magnetic circuit is considered. The new method has many advantages; and the recent articles of Mr. EVERSHED in these columns have shown how easily it lends itself to all calculations needed in the design of transformers. It is, however, defective, since it assumes that every line of force produced in the primary coil threads the secondary circuit. As is well known, magnetic leakage exists to a greater or less extent in all transformers, and to take account of it theoretically is a most difficult problem; indeed, this is the first time that this subject has been attacked in a satisfactory manner.

IN discussing the general character of the results obtained, it must, however, be remembered that the transformer has no influence on the nature of the voltage, EE_1, which is impressed on the primary coil. This, of course, depends merely on the dynamo. Also, as Mr. EVERSHED'S articles have clearly shown, the variation of the magnetism in the core, and therefore of the secondary current, is dependent merely upon the primary voltage; for in all good transformers the number of volts absorbed by the wire of the primary coil is negligibly small compared with the primary potential. It is, therefore, the nature of the primary current, when the secondary is open-circuited, which reveals the character of the transformer itself; and it is unfortunate that the results are complicated in the present instance, owing to the fact that the alternator used for supplying the current had an electromotive force EE_1, represented by two sine waves of different periods, and the amplitudes of which were quite comparable with each other. Had E_1 been a simple sine wave, the influence of the transformer on the primary current could have been distinguished much more clearly.

IN connection with the problem of detecting the various harmonic components of a wave of alternating current or voltage, it may be interesting to recall attention to a Paper of Profs. AYRTON and PERRY read before the Institution of Electrical Engineers on March 28, 1889. On that occasion two electric frequency meters were described, the action of each depending on the principle of resonance. In the first method the current to be analysed was sent through one of the coils of a dynamometer, an alternating current of known frequency being sent through the second. The period of the latter current was altered till an attraction was observed between the coils, and the frequency of each component of the current tested could in this way be found. The other method consisted of passing the current through a stretched wire placed at right angles to the lines of force in a magnetic field. The vibrations of the wire were rendered as large as possible by adjusting its tension or length, and the frequency of one of the components could then be calculated. We may be prejudiced in favour of graphical methods; but we greatly prefer the simple and unmistakable method of superposing a true sine curve on the actually observed curve, and setting off the differences, though the dynamometer and stretched wire methods may be useful where no means are at hand for plotting the curve to be analysed, and the latter, at all events, forms an admirable lecture experiment.

THE *hum* of transformers, alluded to by Dr. FLEMING, forms an interesting subject by itself. In so far as it is due to the reversals of magnetism in the core it is dependent, not on the transformer itself, but on the dynamo and the engine driving it; for the changes of magnetism in the core respond exactly to the electro-motive force of the mains. It may, however, be partially due to action between the currents in the coils and the magnetism in the iron; and in this case it may be expected to change as the load is altered.

A DIFFERENCE of opinion exists as to the importance of the error due to lag, when iron wire coils are used for absorbing the load of alternate-current dynamos. In some cases it amounts to only one or two per cent., but we thought it worth while to ask Prof. EWING for further information on the subject than was given in his recent report on the Parsons Steam Turbine. The result of our enquiries, as we intimated a fortnight ago, was to confirm our estimate of the matter; but Mr. PARKER informs us in a letter, which will be found in our correspondence columns, that his experience is very different. It is a common practice to use a big voltameter for such tests, but the steam and gases boil off in so irregular a manner that accurate readings are very difficult. Such a water resistance was used at Thames Ditton in connection with the experiments on Mordey dynamos, described in our leader on July 17th of last year; and in the same number (*The Electrician*, Vol. XXVII., p 289) we ventured to cast some suspicion on the voltameter method, in consequence of Prof. MENGARINI'S experiments on alternating current electrolysis. It is improbable that any error from lag due to polarisation can exceed two volts, but on a 100-volt circuit that is about the same error which might be expected to arise from the self-induction of iron wire coils.

THE article on "Vertically-lit Lighthouses," which we reproduce from the columns of *The National Observer*, gives some interesting details of the experiments carried out by Lieut. WELLS at the Naval Exhibition. Some correspondence was addressed to the Elder Brethren of the Trinity House by the Secretary of the Shipmasters' Society, in August last, and the experiments at Chelsea were, as far as we have heard, the only recent practical result of the movement; but some very striking trials of "sky flashing" were made in the course of the South Foreland experiments in 1885: three reports on them will be found in Part II. of the Blue Book on this subject. It should be remembered that it is useless to throw a beam of light into the depths of a clear sky; and that it is only when a general haze makes the beam visible as a luminous shaft, or when there are clouds which may be illuminated, that this method can be of any service. In a thick fog on June 25, 1885, the three lighthouses at the South Foreland were all invisible at 1,000 feet, and on many other occasions the lights were lost at 1,200 or 1,300 feet.

Digitized by Google

These thick fogs lie low, and it is under such circumstances that a vertical beam may be seen by vessels outside the fog-bank. A vertical beam would often be visible from a distance when the main light was obscured; but to abolish the ordinary horizontal light altogether, whether in clear or foggy weather, would be very unwise. Since it is impossible to throw, in a haze, the main light to the horizon, Mr. BREBNER and others have designed a system of "dipping" the beam, so that the few square miles of sea immediately surrounding the light which can alone be served, may receive the whole volume of light. The vertical beam might well be used during fogs in conjunction with the syren or bell, and with the "dipping" light if the lighthouse be high enough to make it worth while.

THE subject of electrical radiation is a very attractive one, however problematical its future uses may be. It offers the hope that light may some day be produced without the expenditure of much energy in heat, and that telegraphy may be accomplished without wires. By using radiation, which, unlike light, can penetrate fog, it may be possible, as already suggested in these columns (*The Electrician*, Vol. XXVI, p. 685), to arrange a system of signalling available in foggy weather; and apparently solid walls are no more opaque to these rays than glass is to ordinary light. The able article of Mr. TROUTON, concluded in this issue, will therefore be read with interest; and the close resemblance between optical and electric waves will be fully acknowledged when even the phenomena of thin plates and of the reflection of polarized light are shown to be the same for both.

AS Mr. TROUTON points out, the difficulty in the way of the complete investigation of these radiations is due to the small quantity of energy possessed by them, as at present generated. They die out with great rapidity, and thus produce but slight effect at great distances. If a beam of these rays, radiating several horse-power, could be produced, results of much value would be speedily arrived at. Mr. TESLA'S dynamos produce currents of as great a frequency as 10,000 $\sim$, but this is probably the limit possible with a single dynamo. The ingenious device suggested by Mr. TROUTON deserves close attention, as it appears to point out a way of getting currents of much greater frequency.

IF an alternating current is sent round the laminated field magnets of an alternator whose armature is stationary, an alternating current is generated in the latter, just as if the field magnets revolved under the excitation of a steady current. The effect of revolving the armature, as well as exciting the field magnets with an alternating current, is thus the same as if the field magnets were revolved at one speed (under steady excitation) and the armature revolved independently at some other speed. In fact, the effect of the alternating current in the field magnets is to produce what electricians have lately become familiar with as a rotating field, the speed of rotation being determined by the frequency of the alternating current. The result of the double rotation is to produce an alternating current whose frequency corresponds with the sum or the difference of the speeds according as these are in opposite directions, or in the same direction. If the alternating current in the field corresponds with the rate of revolution of the armature, a current of double this frequency is produced in the latter, as Mr. TROUTON points out. But it appears to us that the method can be carried still further, for by passing this armature current into the field of a second alternator, and revolving its armature at the same rate, a current of the sum of these frequencies, *i.e.*, three times the frequency of the original current, can be obtained.

Lord Rayleigh.—The Queen has been pleased to approve the appointment of Lord Rayleigh to be Lord-Lieutenant and Custos Rotulorum of the county of Essex, in the room of Lord Carlingford, resigned.

Inverness.—The Inverness Police Commissioners last week agreed to ask the Caledonian Canal Commissioners to give the necessary supply of water from the canal, should the Commissioners resolve to introduce the electric light.

Islington.—At a recent meeting of the Islington Vestry, it was decided, after a vigorous discussion, to give a conditional consent to the application by Messrs. Sharp and Kent for a Provisional Order for lighting certain portions of the parish.

Whitehall Club.—A dinner of the electrical engineers who are members of the Whitehall Club is to be held on Friday, the 29th inst., at the Club; it is hoped that Mr. Tesla will be present, unless the postponement of his lecture from the 28th inst. to February 3rd delays his arrival in London.

Royal Society.—The following electrical Papers were down for reading yesterday before the Royal Society:—Major Cardew, "On a Differential Electrostatic Method of Measuring High Electrical Resistances." Prof. Schuster, F.R.S., and A. W. Crossley, "On the Electrolysis of Silver Nitrate in Vacuo."

Another Columbian Exhibition.—An Exhibition in commemoration of the discovery of America by Columbus is to be held at Genoa, in Italy, during the present year. The whole of the Exhibition building and grounds will be lighted by electricity, the contract for the installation having been given to Messrs. Schuckert and Co., of Nuremberg.

Electrical Bills in Parliament.—Among the Bills which have passed the Examiners on Standing Orders of the House of Commons, are those of the St. Pancras Vestry, the City and South London Railway, and the Hampstead, St. Pancras, and Charing Cross Railway. In respect to the proposed Waterloo and Royal Exchange Railway there was no appearance on behalf of the promoters, and the Bill was struck out of the list.

The Crystal Palace Exhibition and Railway Rates.—The London Chamber of Commerce recently approached the London, Brighton, and South Coast, and the London, Chatham, and Dover Railway Companies with a view of securing a reduced rate on exhibits intended for the Electrical Exhibition at the Crystal Palace. The Companies did not see their way, however, to grant reduced rates, but have now agreed to convey the *unsold* exhibits on the return journey, free of charge, to any station on either of these lines of railway, provided that the exhibits remain the property of the exhibitors.

Street Electric Lighting in St. Pancras.—The Electricity Committee of St. Pancras made some experiments in the early hours of Saturday morning by testing the arc-lights placed along the centre of Tottenham Court-road. Prof. Robinson and Mr. Alderman Gibb accompanied the committee; and after all the business houses were closed the electric light was, first of all, put on, and the street lamps put out; then the case was reversed; and the contrast is said to have exceeded the most sanguine expectations, the 12 electric lights giving

Digitized by Google

considerably more light than the 85 ordinary street lamps. The experiments were regarded as very satisfactory.

The Metropolitan Telephone System.—A meeting of the General Telephone Committee appointed by the Council of the London Chamber of Commerce to inquire into and report upon the general position of telephony in London, met on December 18, 1891, and considered a list of complaints preferred against the National Telephone Company. Colonel Jackson and Mr. Sinclair gave what were deemed satisfactory explanations on behalf of the Company, and it was agreed to recommend the Council of the Chamber to press the Government to confer statutory powers, it being urged that only by this means can an efficient telephone service be secured throughout the Metropolis.

The Liverpool Overhead Railway.—The Directors of this railway recently paid a visit to Birmingham for the purpose of inspecting a carriage which has been constructed for them at the works of Brown, Marshall, and Co., Saltley. The pattern carriage is 45ft. long and 8ft. 6in. wide, runs on bogey wheels, and is arranged with a gangway from end to end. There are three compartments—one first-class for 16 passengers, and two third-class compartments for 20 each, with an end compartment for the driver. The weight of the carriage, including the motor, is 14 tons. The Liverpool line is about 6½ miles long, and there will be 13 stopping places, including the termini. It is intended to charge a universal fare of 2d., with 1d. extra for first-class. The carriage was approved, and 30 similar ones are to be constructed.

Old Students' Association.—We are asked to announce the fact that Mr. Reginald J. Jones has been obliged to resign (owing to pressure of professional work) the Hon. Secretaryship of the Old Students' Association, which he has held since the beginning of the session 1890-1. The Association has secured the services of Mr. E. B. Vignoles as Hon. Secretary and Hon. Treasurer, and Mr. A. E. Ruddock as Assistant Hon. Secretary. All correspondence and subscriptions should in future be sent to E. B. Vignoles, Hon. Secretary and Hon. Treasurer, O.S.A., 28, Lanhill-road, Elgin-avenue, W. The membership of the Association is steadily increasing: last session 62 members and associates were elected; while this session, up to December 31st, no less than 38 members and associates have been proposed for election.

The City Lighting.—As stated in our City Notes, the City of London Electric Lighting Company has issued the balance of its ordinary shares at 5s. per share premium, and, accompanying the circular published in reference to this issue, the Directors give an account of the progress made by the Company, in which they state that current is now being supplied from the two generating stations situate at Meredith Wharf, Bankside, and at Wool Quay, Lower Thames-street, E.C., and that the erection of additional generating plant is being proceeded with. Queen Victoria-street, Gracechurch-street, King William-street, and Cornhill are already lighted, and in a few weeks a number of the main thoroughfares of the City will also be lighted. The Mansion House was lighted from the Company's mains in December last. Since then the engineering staff has been continuously employed in connecting the premises of further customers. Signed applications for about 13,000 lamps have been already received, and are being added to at the rate of 1,500 a week.

The London County Council and Overhead Wires.—We have received a copy of some correspondence between the Secretary of the London Chamber of Commerce and the London County Council, in reference to the recently-issued overhead bye-laws. The Chamber of Commerce asks the County Council to furnish it with the reasons which led the Council to issue the regulations in question, and states that several members of the Electrical Trade Section affirm that it will be impossible to carry on their business if the regulations are strictly enforced, and that it is proposed to hold a meeting in order that representations may be made on the subject. The County Council replies that it advertised the regulations in *The Times*, and sent copies out for the information of all firms concerned. The Council further states that before making a formal application to the Board of Trade for confirmation of the bye-laws, it is prepared, as also is the Board of Trade, to consider any objections or observations which may be offered with regard to them by any persons interested. Any such representations should be sent to the Council and the Board of Trade some time before the end of the month.

Obituary.—We regret to record the death, at his residence at Gipsy Hill on the 16th inst., of Mr. W. Lewis Wells, at the age of fifty-six. Mr. Wells entered the service of the Electric and International Telegraph Company at an early age, and became head of the clearing house, retiring with a pension on the acquisition of the inland telegraphs by the Government. He joined Messrs. Glass, Elliot and Co., as accountant to the Malta and Alexandria Telegraph Company, in 1858, and was also accountant to the Telegraph to India Company during its short existence. In 1870 he entered the service, as traffic accountant, of the seven Associated Submarine Cable Companies, which had grown out of the Malta and Alexandria Company, and which were amalgamated into the Eastern and Eastern Extension Telegraph Companies; and in this capacity attended the International Telegraph Conferences at Rome, St. Petersburg, London, Berlin, and Paris. He was also secretary of the Submarine Cables Trust and a Fellow of the Statistical Society. For many years Mr. Wells suffered from chronic bronchitis, and finally succumbed to an acute attack of that disease. He was much respected, and his loss will be regretted by the telegraph world.

Association for the Improvement of Geometrical Teaching.—The eighteenth general meeting of the Association for the Improvement of Geometrical Teaching was held at University College on January 16th. The following were elected to serve on the council for the current year:—*President*: Rev. C. Taylor, D.D. *Vice-Presidents*: R. B. Hayward, M.A., F.R.S.; R. Levett, M.A.; Prof. G. M. Minchin, M.A.; and R. Tucker, M.A. *Treasurer*: Prof. A. Lodge, M.A. *Hon. Secs.*: E. M. Langley, M.A., and C. Pendlebury, M.A. *Other Members of Council*: Mrs. Bryant, D.Sc., F.C.P.; C. V. Coates, M.A.; R. F. Davis, M.A.; A. S. Eve, M.A; C. Heppel, M.A.; Prof. W. H. Hudson, M.A.; Rev. S. S. Milne, M.A.; Prof. W. N. Stocker, M.A. The following papers were read:—"On Approximate Calculations" (Prof. A. Lodge), "On Laguerre's Dictum concerning Direction" (Prof. R. W. Genese), "On the Geometrical Interpretation of Fallacy in Elimination" (Prof. R. W. Genese), "On the Use of Horner's Method in Schools" (Mr. E. M. Langley). An informal address on the Geometrical Treatment of Infinite Complex Series was given by Mr. R. B. Hayward.

The Chicago Exhibition.—The French Government is stated to have asked for some 154,000 square feet of space at the Chicago Exhibition. Of this amount, 110,000 square feet are required in the Hall of Manufactures, 11,000 feet in the Cattle Show, and 33,000 square feet in the Fine Arts Gallery. Neither the Electricity nor Machinery Hall is included in this demand, and more space will, therefore, probably be asked for.—The necessary machinery for furnishing power to the Exhibition is being secured practically free of cost, manufacturers of engines, pumps, &c., being ready to supply power gratuitously. Some 50 separate contracts are to be let for the electric lighting of the Exhibition buildings and grounds. In all there will be used, according to present plans, approximately 127,000 electric lamps, of which 7,000 will be arc, of 2,000 c.p. each, and 120,000 incandescent 16 c.p. lamps. To run the plant 22,000 H.P. will be required. By the awarding of separate contracts for the lighting of each of the buildings and of different sections of the grounds, all electric firms, whether large or small, will have an opportunity to participate and to show what they can do, and at the same time a variety in illumination will be effected. In the great Manufactures building alone there will be 33,000 lights. The plans prepared by the electrical experts call for ten times the capacity of all the plants used at the Paris Exhibition. The Directors will spend $1,000,000, and perhaps more, for these electric plants. Exhibitors will not be required to pay anything for light, except in cases where they call for more lamps than are furnished by the construction department. In that event they will be furnished with additional lamps at actual cost.

THE HARMONIC ANALYSIS OF TRANSFORMER CURVES.*

BY DR. J. A. FLEMING, M.A.

1.—The Harmonic Analysis of Currents and Electromotive Force Curves.—The method by which the curves representing the instantaneous values of the current and E.M.F. in any alternating-current circuit are obtained has been before explained (see *The Electrician*, Vol. 24, p. 239, 1890). It has also been shown ("Alternate Current Transformer," Vol. I., chap. III. § 3) how any single valued function of this form—that is, any non-intersecting and single-ordinate curve—can be resolved into a series of simple sine curves. That is to say, any such curve, however irregular, can be built up by adding together the ordinates of a series of simple sine curves

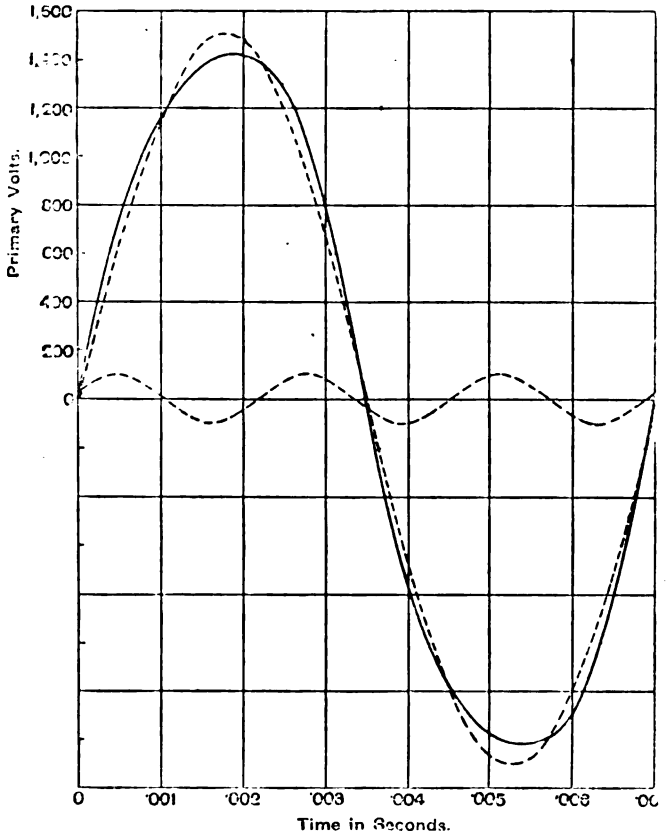

Fig. 1.—Harmonic Analysis of the Curve of Primary Electromotive Force of 10-Light Westinghouse Transformer. Dotted Curves represent the Harmonic Components.

whose wave-lengths successively decrease. In their investigations on transformers, Messrs. Ryan and Merritt obtained a large series of such transformer curves, some of which they have thus analysed and resolved into their harmonic constituents. The results of this work are shown in the appended diagrams.

Whatever may be its form, the equation of the curve can in every case be expressed in accordance with Fourier's Theorem by a series of sine and cosine terms, and we can write the instantaneous value x of the current or E.M.F. as expressed by the series

$$x = A_0 + A_1 \sin pt + A_2 \sin 2pt + \text{etc.} + B_1 \cos pt + B_2 \cos 2pt + \text{etc.}$$

In which the constants A_n and B_n are determined by the equations

$$A_n = \frac{2}{T}\int_0^T x \sin \frac{2\pi n t}{T} dt,$$

$$B_n = \frac{2}{T}\int_0^T n \cos \frac{2\pi n t}{T} dt.\dagger$$

Messrs. Ryan and Merritt determined the arithmetic values of these constants for all the observed curves. When the primary impressed E.M.F is thus analysed it is found that it can be expressed very nearly by four terms of the following Fourier series:—

$$E_1 = 1{,}500 \sin pt + 100 \sin 3pt - 42 \cos pt + 28 \cos 3pt.$$

Graphically it can be represented as in Fig. 1, where the dotted curves show the principal and secondary components of the original (firm line) curve. The primary E.M.F. is thus seen to be made up of a principal sine curve and a first harmonic of one-third the wave length. In the same way the secondary electromotive force was analysed and found to consist of a principal component and an harmonic of one-third the wave length (*see* Fig. 2). The expansion in harmonic terms for the secondary electromotive force being nearly

$$E_2 = -76{\cdot}2 \sin pt - 4{\cdot}8 \sin 3pt + 2{\cdot}7 \cos pt - 0{\cdot}1 \cos 3pt.$$

We shall not be far wrong in assuming that in all cases the curves of primary and secondary electromotive force are not very far removed from sine curves, and treating them accordingly. Doubt has been frequently thrown on this by some writers who have even ridiculed the assumption that the simple sine curve can express the form of the curve of electromotive force of any alternator; but strict investigation proves the assumption warrantable.

Moreover, an inspection of the indicator diagrams shows us that the phases of the primary and secondary electromotive forces are exactly opposite to one another, or differ by 180deg., when there is no secondary load on the transformer, but that when there is a secondary load the secondary electromotive force is a very little in advance of the primary in phase.

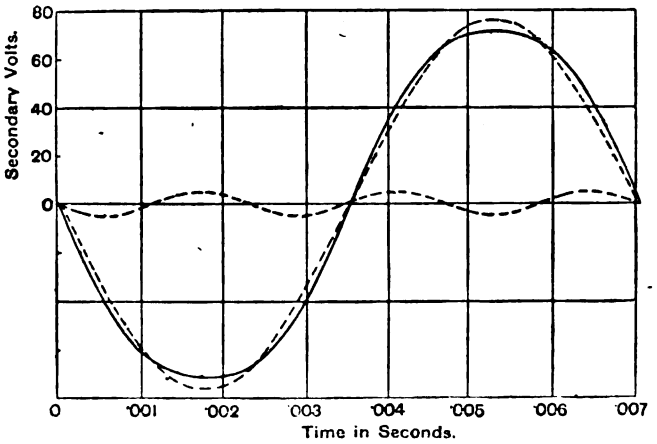

Fig. 2.—Harmonic Analysis of Curve of Secondary Electromotive Force of 10-Light Westinghouse Transformer.

It is quite different, however, with the primary current. We see by the eye, that when there is no secondary load the primary current curve is very far from being a simple sine curve. Messrs. Ryan and Merritt found that for the transformer they used the primary current curve could be analysed into three harmonic components (*see* Fig. 3), of which the wave lengths are respectively in the ratio, 1 : 3 : 5, and that it is expressible by the series,

$$i = 0{\cdot}129 \sin pt - 0{\cdot}148 \cos pt + {\cdot}011 \sin 3pt - {\cdot}047 \cos 3pt - {\cdot}016 \cos 5pt.$$

We might express the results of this harmonic analysis by musical notation. The middle C on pianoforte is a note having a frequency of 256. Hence the lower G on the base clef has a frequency of about 96; and, accordingly, the ordinary frequency at which transformer currents are worked being about 100, this is represented very nearly by the note

The note whose frequency is three times this is very nearly the lower F on the treble clef; and that whose frequency is

* These articles form part of Vol. II. of "The Alternate Current Transformers in Theory and Practice." All rights reserved.

† For the proof of this theorem the student is referred to Todhunter's 'Integral Calculus," Chap. XIII. Also Greenhill's "Integral Calculus," §183.

Digitized by Google

five times is the upper C on the treble clef. Hence the harmonic constituents of the primary current curve represented in Fig. 3 can be denoted very nearly by the musical chord

It would be interesting to see if a very acute musical ear could analyse the *hum* of transformer at work into its constituent simple notes.

If we inquire the cause of this distortion of the primary current the reply is that it is due to the hysteresis of the iron. If hysteresis were altogether absent the curve of primary current with open secondary would be a sine curve, lagging 90deg. behind the primary E.M.F. as represented by the dotted curve in Fig. 5. If eddy currents were set up in the core to any extent the effect of these would be to cause the primary current

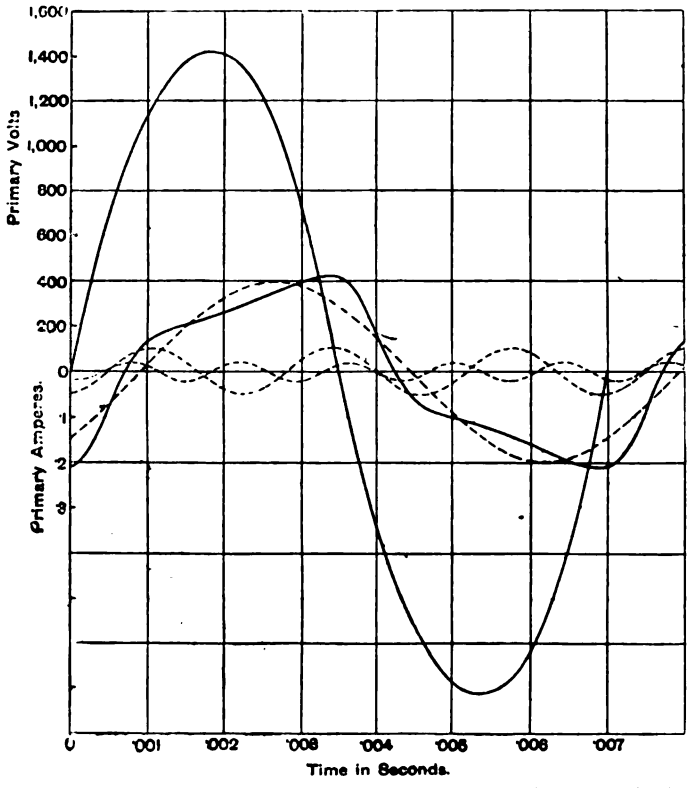

FIG. 3.—Harmonic Analysis of Curve of Primary Currents of the 10-Light Westinghouse Transformer on Open Secondary Circuit. The Curve of Primary Electromotive Force is also shown.

to be accelerated in phase or brought more into synchronism with the impressed E.M.F. If, in addition, hysteresis is present the result will be to make the current curve unsymmetrical in shape as we see it is. As the load on the transformer secondary circuit is increased the primary current curve is brought back more and more into synchronism with the primary impressed E.M.F., and in its final position it comes into almost exact opposition with the *secondary* electromotive force, losing its unsymmetrical form and approximating more to a simple sine curve; and its harmonic analysis shows that as this loading up of the secondary circuit takes place the principal sine term of the Fourier series for the current becomes more important than the subsidiary terms.

When the transformer is fully loaded up on its secondary circuit we see that the secondary electromotive force lags a little behind the primary electromotive force, that is, it is not exactly opposite to it in phase. This is due chiefly to magnetic leakage. The primary current is under these circumstances almost exactly opposed in phase to the secondary electromotive force. Under conditions of full load none of the curves of electromotive force and current depart very widely from simple sine curves, and at any rate the sine curve form is sufficiently correct to allow of the application of simple analytical treatment in developing the theory of the transformer and in calculations. The marked exception to this is the primary current at low loads or the magnetising current.

Prof. Ryan and Mr. Merritt repeated the same kind of experiments with a 40 light Westinghouse transformer, and also with a transformer having a core made of iron wire; but the general results as to the form and relative phases of the current and E.M.F. curves were found to be of the same character as in the above experiments.

Messrs. Humphrey and Powell also studied, by this method, a 40-light Westinghouse transformer, and found the loss on open circuit to be only one-half that of the 10-light. Its efficiency at the full load was 96·2 per cent., equivalent to an all-day efficiency of 90 per cent. This improvement is due to the use of a better grade of iron.

(To be continued.)

VERTICALLY-LIT LIGHTHOUSES.

The following article appeared in the *National Observer* of Saturday last, over the signature of "Kenneth Cornish":—

That eminent mechanician and man of science, the late Lieut.-Colonel Alexander Strange, F.R.S., who was the grandson of Scotland's great Jacobite engraver, Sir Robert Strange, and inherited his grandsire's delicacy of touch and vision, had a favourite saying: "Everything that is is wrong." Though at first sight paradoxical, there is a marvellous amount of truth in it, especially as regards scientific theory and practice. The whole history of scientific progress proves it, for most real discoveries have had bitter and powerful enemies in those whose preconceived notions were thereby traversed. In comparatively modern times, Harvey and Jenner in medicine, James Watt and George Stephenson, Arkwright, and the grand company of industrial inventors, attest the fact. The truth of Colonel Strange's apophthegm was illustrated by the success of experiments in the vertical illumination of clouds during the last three months of the Royal Naval Exhibition. Ever since the old-fashioned beacon as employed by night to warn mariners off dangerous rocks and coasts was quenched by the men of science who revived the old Greek Pharos as the modern lighthouse, much ingenuity and cash have been expended to prevent the rays of light employed from passing upwards, or in any save a horizontal direction. The endeavour has been made to rear very lofty lighthouses, crowned by lanterns—now mostly of the revolving type—carrying lights of enormous intensity, which pass into the night in a horizontal direction through lenses of immense and constantly increasing power and cost, the nominal power being estimated at a maximum at St. Catherine's of six millions of candles, and at the Eddystone of five millions. The photometer, on the basis of which these figures are estimated, is a most illusory instrument, however, as it merely gives the relative intensities of lights on an arbitrary scale; the more important quality of diffusibility it ignores, while traders on the so-called candle-power carefully omit to say—probably few of them know—that this diffusibility diminishes in a regular ratio with the square of the intensity. Now, the extreme distance at which Eddystone light is visible from a ship's deck on a clear night is stated to be seventeen and a-half miles; and probably the reflection from the few rays which manage to escape at its crown may be seen as a kind of halo some miles further, the lantern being about 180ft. above water-level at high tide—just that of the truck of the most useful old 74-gun line-of-battle ship.

The cost of building and maintaining the lighthouses on our shores is very onerous, and all save those interested in maintaining the present system by the powerful *argumentum ad crumenam* must rejoice at, and do their utmost to support, an infinitely cheaper and at the same time much more efficient scheme. A young Scots shipmaster, Captain Robertson, of the "Mogador" s.s., by a brilliant inspiration, came to the conclusion that a light sent vertically upwards would not only be seen as a bright pillar against the horizon, but illuminate the clouds above it, and thus be visible at a greater distance from the sea and other levels than any horizontal light, however powerful. He saw—what was evident when he had once pointed it out—that, even in fog, the vertical light would be far more easily seen than the horizontal, though the vessel herself were enveloped in the mist, because the curtain thins rapidly on leaving earth or water, and does not rise more than

Digitized by Google

300ft. at the outside. It rarely happens in the thickest fog that one cannot see the main-truck from the quarter-deck, while the mainmast itself is quite invisible. A mile or so of fog will absorb the most powerful light, which will not, however, be invisible to vessels in clear water outside the belt of obscurity. Yet the vessels in the haze would be able to descry all but the lower rays of a vertical light. Captain Robertson communicated his discovery at the end of June to his friend, Captain A. G. Froud, Lieutenant R.N.R, the secretary to the Shipmasters' Society, who consulted the writer about it, with the result that the matter was at once laid before Lieutenant Lionel Wells, R.N., at the Royal Naval Exhibition; and this officer, being a man of science and learning, did not lose an hour in putting the theory to the test. The same evening he sent beams of light upwards in our presence, and the results exceeded our sanguine expectations. The first he projected, at an angle of about fifteen from the zenith, as a broad belt from the Admiralty search-light at the side of the little glass house on the lake, whence he directed torpedo operations and other manœuvres. It went up, as far as we could estimate then—and later experience showed we had greatly under-estimated the distance—about 500 yards, and illuminated a passing cloud at the lower level very distinctly. He then narrowed the beam into a beautiful pencil of light, that we estimated at 1,000 yards in length, which caught a cloud on the higher level. Finally, he managed to adjust the instrument so that the light-pencil became vertical. The effect was extremely fine; but in about half a minute the mirror was broken by the intense heat of the melting carbons. These lights were seen distinctly at Wimbledon. Lieutenant Wells repeated the experiments till the Exhibition closed, the results being watched by volunteer observers. The lights were clearly visible at Frant, 34 miles away, although they were only set at an angle of 15. Had they been vertical they would have been visible for 50 miles at least. The light used in these experiments was estimated at 6,500 candles intensity, that of the model of the Eddystone in the grounds being really of about 300,000 candles intensity. Though *caviare* to the general, these experiments were of interest and value to experts and scientific seamen, and were, perhaps, the most important of the many good works done at the Exhibition.

They attracted the notice of the Admiralty, the Trinity House, and Thames Conservancy, as well as the Board of Trade and Lloyd's; but hitherto it has not been possible to show the most valuable feature of the discovery, by placing an absolutely vertical light in a suitable position for observations to be taken at sea. The data which a beam of light going up some thousands of feet vertically—it must be absolutely vertical—would give for the determination of a ship's position is such that in tolerable weather the distance should by trigonometrical observation be fixed to a cable's length. There is no difficulty in the construction of a suitable apparatus at a small cost, and an admirable site and opportunity for the erection of the first vertical light for maritime service have occurred to the writer. The erection would be in many respects a suitable memento of the Royal Naval Exhibition, and of the fact that the first vertical light experiments were conducted within its bounds. An octagonal column near Portisham—about two miles from the Chesil Beach, on a hill 790ft. high, which dominates the Portland Bill and commands the Great Bridport and Weymouth Bays—was erected by public subscription to the memory of that Dorset man, Admiral Sir Thomas Hardy, flag captain to Nelson, who died in his arms. It was planned as a lighthouse by the architect, the late Arthur Acland, brother of the venerable Sir Henry Acland, Bart., Regius Professor of Medicine to the University of Oxford, and is owned by Mr. William Manfield, of Portisham, who is the descendant of one of Hardy's three daughters, the sole survivor of whom is Lady Macgregor. Visible from the sea for about 50 miles, the monument, which is falling into ruin, is even now a valuable landmark by day. Experienced seamen say that a vertical light placed at this point would be of enormous value, as the coast is one they dread and shun even more than St. Catherine's Point. It is estimated that the tower could be repaired, a caretaker's cottage built, and the necessary apparatus for a sufficiently powerful vertical light set up, for between £1,000 and £1,200. The idea has been broached and favourably received in Dorsetshire, by Mr. Manfield and all to whom it has been suggested, and no doubt the County Council would vote a sum for the work if it were backed up, as it should be, by the Government departments, the great steam-shipping companies, and the railway companies which have sea lines, as well as by Lloyd's and other mercantile bodies. The saving in life and property if this new system does half what is expected of it would be simply incalculable. Meantime, it looks very much as if it supported the dictum of Colonel Strange.

BOOKS, &c., RECEIVED.

"Electric Light Cables and the Distribution of Electricity." By Stuart A. Russell. The Specialists' Series. (London: Whittaker and Co.).

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, January 22nd.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "On the Driving of Electro-magnetic Vibrations by Electro-magnetic and Electrostatic Engines." By Prof. G. F. FitzGerald, F.R.S. (2) "On Supplementary Colours." By Prof. S. P. Thompson, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening discourse: "The Composition of Water." By Lord Rayleigh, F.R.S.

SATURDAY, January 23rd.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "The Induction Coil and Alternate Current Transformers." By Dr. J. A. Fleming, M.A.

MONDAY, January 25th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. II.—1. "Developments of Electrical Distribution." By Prof. George Forbes, F.R.S.

TUESDAY, January 26th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be further discussed: "On Weighing Machines." By Wilfrid Airy, B.A., M.Inst.C.E. After which the President and Council will hold a reception in the Library.

WEDNESDAY, January 27th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Annual General Meeting. Election of Officers. Presidential Address by Baldwin Latham, M.Inst.C.E.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Scientific Value of Lovibond's Tintometer." By F. W. Edridge-Green.

THURSDAY, January 28th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting. Presidential Address on "Electrotechnics." By Prof. W. E. Ayrton, F.R.S. (Postponed from the 14th inst.)

UNIVERSITY EXTENSION SOCIETY.

8 p.m. Lecture at Public Library, Lavender Hill, on "Recent Applications of Electricity." By Dr. J. W. Waghorn.

FRIDAY, January 29th.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Papers to be read: (1) "The Evolution of Rotating Projectiles." By William H. D. Cleminson, Stud. Inst. C.E.; (2) "The Manufacture of Forged Steel Projectiles." By D. Carnegie, Stud Inst. C.E.

ROYAL INSTITUTION

9 p.m. Evening Discourse. "Tales of the Scottish Peasantry." By Sir George Douglas, M.A.

SATURDAY, January 30th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture. "The Induction Coil and Alternate Current Transformer." By Dr. J. A. Fleming, M.A.

*** Particulars of meetings to be held or Papers to be read before Scientific Societies during the ensuing week should reach us not later than Thursday, 6 p.m.

Purification of Water by Electricity.—Dr. Fermi, of Munich, has been testing the Webster method of purifying water by electricity. The dissolved organic substances are reduced about one-half, and the suspended substances are either precipitated to the bottom by the ferric hydrate formed on the surface of the iron electrodes, or gather on the surface of the water. The smell of the water is also perceptibly improved. After detailing the process and explaining the chemical action that arises during the purification, Dr. Fermi says that the organic substances contained in a litre of water can be reduced by two-thirds in one hour by an electric current of 0·5 to 1·9 with ampere flat iron electrodes 80 sq. cms. and 5 cms. apart. The number of germs is thus diminished fifty or one hundred-fold. The purifying effect of such current, however, is less reliable than that of the addition of 1 per cent. of lime, which completely frees the water of germs and keeps it free, whereas in the electrified water the germs multiply again fivefold in forty-eight hours.

SPECIAL NOTICE.

We have in preparation a fine Steel-Plate Portrait of Professor W. E. AYRTON. F.R.S., President of the Institution of Electrical Engineers, which will be issued with the next or subsequent number of "THE ELECTRICIAN."

NOW READY.

Volume XXVII. of "THE ELECTRICIAN," price 12/6; post free, 13/6. abroad postage extra.

ALSO NOW READY.

Cases for binding Volume XXVII., price 2/0; post free, 2/3.

THE DEVELOPMENT OF PRACTICAL GEOMETRY.

In the two letters which Mr. LANGLEY has sent us, the question raised by Mr. OLIVER HEAVISIDE as to the doings of the Association for the Improvement of Geometrical Teaching has been fully answered. In inviting this information we must confess that we were not so much concerned with the better teaching of geometry as with the development of that science. It has always appeared to us that there are two distinct kinds of mathematical mind, the geometrical and the analytical; but this is denied by many mathematicians. They say that the two are as inseparable as melody and harmony, and that a mind which is content with geometry to the exclusion of symbolic mathematics is to be compared to a musician who can take pleasure in playing the Hallelujah Chorus on a flute. The metaphor is a bad one. One man cannot manipulate a whole orchestra, and very few performers are privileged to produce more than one note at once. However that may be, the value of the application of geometry to electrical work is inconceivable to those who have had no practical experience in it; and while graphics are taught by Prof. ROBERT SMITH, and by Prof. KARL PEARSON, and a few others, progress is only being made in this direction by those who use geometry for practical work. Nineteen schoolmasters out of twenty, and almost as large a proportion of professors, are content to teach what they call geometry out of a book written for the schools of Alexandria sixteen hundred years ago. Euclid is not useless; but its real value to-day is for teaching logic, not geometry. HOBBES studied Euclid; but his habit of mind was analytical, and not synthetical. He therefore began at the famous forty-

Digitized by Google

seventh proposition, and worked backwards to the beginning, after which he was, no doubt, in a better position to appreciate the definitions, axioms, and postulates than most students who attack these first. But most minds are inclined to inductive and not to deductive reasoning. Students of science, more particularly, perhaps, those who turn their attention to physics, are more interested in pioneering advance, and in drawing inferences from observed phenomena, than in groping backwards from experience for causes which may make that experience rational.

For educational purposes, the building up of knowledge step by step is obviously best as a general principle, while the analysis of a problem is an excellent test of knowledge already acquired. A vast majority of mathematical work appears at first to be analytical; but, on closer examination, it will generally be found to be made up of synthetical constructions. A schoolboy is first invited to exercise his powers of guess-work when he begins to do simple division, and to a greater extent when he extracts square roots. The process is a succession of guesses, each step supplementing the last, and correcting the error. Algebra is full of guess-work, which has to be done according to laws. The real meaning of these restrictions, if ever carefully taught, is generally quickly forgotten, and the work proceeds, just as a game is played, by rules. In the working of the differential and integral calculus the guess-work and the rules are more prominent than ever, and the higher the problem, the more important part does guess-work play, while the real signification of "the rules of the game" is so often lost, that if we stop a mathematician in the midst of his work, and ask, "But why do you suddenly introduce $\log_e a$, when no logarithms have been mentioned?" he will reply, "Oh! that is one of the things you *have* to do, one of the first things you learn in integrating." It is indeed one thing to carefully study the meaning of each of these dodges, and it is another thing to have them ready for use at one's finger ends. To attack a problem by algebraic or so-called analytical methods may be compared to the entry of an unknown fortress by means of a bunch of keys. Each trick of manipulation or other "well-known substitution" is a key, and the proper one has to be selected for each locked door that is met with. The reasons for the shape of each key, the number and the form of its wards are forgotten, if indeed they were ever studied. It might be thought that, with patience, anybody might go through the whole bunch one by one, until the bolt was shot. Not so in mathematical work: he who would successfully wield the key must know how to manage the levers and coax the tumblers; he must know when the door has been opened, and which way he must turn next. But it is possible to enter a fortress by another route than a labyrinth of dark passages and locked doors. It is possible to penetrate to its innermost court without once losing sight of the light of day or of the direction of march. A straight ladder or two is all that is needed, with a little agility, some constructive skill in placing them in effective positions, and mechanical instinct in the best way of bridging wide gaps. With the destination always in view, and a clear reason for each step, this process is to many minds more satisfactory. By this route we "get there," though it may sometimes be a little roundabout. Geometrical construction is the name of this route, and as yet it is hardly to be dignified by the name of mathematics.

Graphics are treated by many mathematicians as a specially prepared food for infants; strong meat cut up small for feeble digestions. They look rather condescendingly on such methods as not fit to be classed with either pure or applied mathematics, but as useful helps for ignorant engineers. After all, nothing more is wanted than plenty of straightforward geometry. We have constructive geometry and descriptive geometry, and some other minor branches; but a large part of the subject is composed of such useless stuff as conic sections, pedal curves, and the like. These may have some educational value as pure mathematics, but we are dealing at present with practical applications, and maintain that a large number of engineers, though not all, could use geometrical methods, if they only knew how, to solve many problems which they now shirk for the simple reason that their algebra is rusty from long disuse. In a geometrical construction, little is, as a rule, assumed, and there are very few tricks. Take the case of solid angles as an example. A student has the expression $2\pi\ (1 - \cos\theta)$ flung at his head; and whether he understands it or no, he finds that it is one of the proper keys to use in dealing with solid angles. During his classical studies rather than his mathematical, he will perhaps hear of the figure which Archimedes desired should be cut on his tombstone, a sphere inscribed within a cylinder, to commemorate his discovery that the two curved surfaces were equal. The proof of this, for proofs are wanted for educational purposes, is as charming as the $2\pi\ (1 - \cos\theta)$ is repulsive; and it is not until the former is mastered that the latter can be appreciated.

In many books a section is devoted to curve-tracing. During the past ten years electrical engineers have become well accustomed to curves, and handle them and their axes and asymptotes in a way which must horrify some mathematicians. They plot curves for the purpose of arriving at certain results; and, stepping in where angels fear to tread, "they get there," while the analytical mathematicians are still floundering after a formula. How little is to be found in text-books on the various ways of setting about to find the rational formula, or even an empirical formula for an observed curve!—another instance of the comparative unpopularity of deductive reasoning. Some dodges are taught at technical colleges, but as yet this is not considered as part of practical geometry. The "clock-face" methods of Blakesly and Kapp are examples of a most useful application of geometry to problems which are simply bewildering in symbolic notation, and a hitherto unpublished polar method on Zeuner's valve-diagram principle has been devised by Prof. S. P. Thompson, to include other periodic fluctions than simple harmonic ones. In the subjects of the practical properties of conic and polar curves alone, there is a wealth of useful information unknown to nine engineers out of ten; and the tenth has laboured through theorems and problems of a purely academical character, and has only found them scattered here and there through sundry books. We have marked some of them with blue pencil, as being the only parts worth having in certain text-books. A dictionary of the characteristics and properties of curves, with a few practical corollaries, like Carr's Synopsis, but one-tenth the size, would be very valuable. Proofs would be as much out of place in such a book as in Molesworth.

We do not appeal to men who prefer to "play upon the symbols." At least one well-known engineer prefers a double column of figures to a curve plotted from them, and more than one of our valued contributors prefer a fine flowing formula to a geometrical figure. But we appeal to those who, like the members of the Association for the Improvement of Geometrical Teaching, may be able to move the whole mathematical school of this country, to improve not only the method of teaching of geometry set forth by Euclid, but to infuse into geometry itself some of the spirit of his mighty contemporary Archimedes, and to place in the hands of engineers and physicists an operator which, if not as powerful as any algebraical calculus, is one which can be handled by the plain man.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 273.*)

§ 52. **Maxwell's Method.**—In order that we may be able to calculate the action of one coil on another, we must know M, the coefficient of mutual induction for the two coils. Maxwell gives a very general expression by which we can calculate M to any accuracy required. To fully understand Maxwell's process requires a knowledge of the elements of Spherical Harmonics. As we do not assume this knowledge on the part of our readers, we shall only explain Maxwell's result. Suppose, then, that we have two coils of radii A and a, and that they are so placed that their axes* meet at an angle θ in a point O (Fig. 46).

Maxwell shows that

$$M = G_1 g_1 P_1(\theta) + G_2 g_2 P_2(\theta) + \ldots \ldots$$

where the big G's depend upon the dimensions of A, and the distance of its centre from O, and the little g's depend in a somewhat similar manner upon the smaller coil. A is supposed to be greater than a. The quantities $P_1(\theta)$, $P_2(\theta)$, &c., are

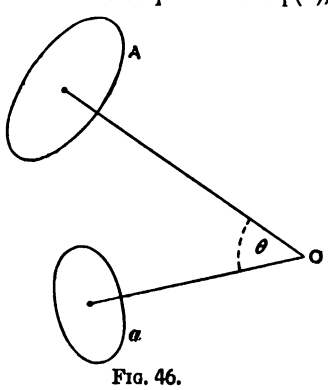

Fig. 46.

Zonal Harmonics; they are simply functions of θ, whose values can be found by the aid of a table of sines and cosines. Thus—

$$P_0(\theta) = 1,\ P_1(\theta) = \cos(\theta),\quad P_2(\theta) = \tfrac{1}{2}(3\cos^2\theta - 1)$$
$$P_3(\theta) = \tfrac{1}{2}(5\cos^3\theta - 3\cos\theta).$$

A table of their values for successive values of θ is given by Prof. John Perry in the *Phil. Mag.*, Dec., 1891. It is important to note that when $\theta = 0$ $P_0 = P_1 = P_2 = \ldots = 1$.

§ 53. **Zonal Harmonics.**—These functions are extremely useful in many physical problems. A study of Chapter XIV., Vol. II., of Maxwell's treatise will show the student that it would be very hard to imagine that there could be any set of functions better adapted to express the physical facts than Zonal Harmonics. The following may serve to give some ideas as to their nature. We know (§ 17) that the magnetic potential of a pole of strength m is $V_0 = m/r$. Again, the potential of a "small" magnet of length l and pole-strength m is $V_1 = m\,l\cos\theta/r^2 = m\,l\,P_1(\theta)/r^2$, where θ is the angle between the axis of the magnet and the radius r. Let O be the centre of the magnet. Let us now move the magnet in the direction in which its north pole points through a distance $l/2$, and then place a second magnet exactly equal to it in all respects, with its centre at a distance $l/2$ on the opposite side of O, and pointing in the opposite direction. If we determine the potential of this new system, we find $V_2 = 2\,m\,l^2\,P_2(\theta)/r^3$. We can do this by a method similar to that of § 18; but in applying it we must remember that θ changes as well as r. If we repeat this operation with this last system and place on the opposite side of O a second system in which the signs of all the poles are reversed, we find that $V_3 = 2\times 3\,m\,l^3\,P_3(\theta)/r^4$, and so on. If we examine these different cases we see that they are equivalent to systems of isolated poles.

Thus V_0 is the potential of a single pole m, V_1 that of two poles $+m$ and $-m$, V_2 that of poles $+m$, $-2m$, $+m$, and so on, the various cases being shown in Fig. 47. The coefficients in the nth case are those of the successive powers of x in $(1-x)^n$. The potential of any system of magnets or currents which is symmetrical about an axis can always be expressed as a series of Zonal Harmonics with suitable coefficients.

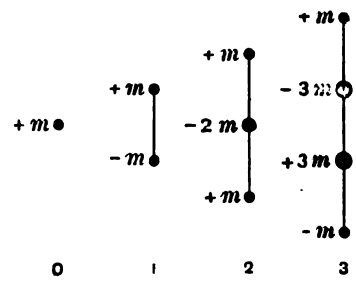

Fig. 47.

§ 54. **Values of G and g.**—These quantities can be found in the following manner. Let B be the distance of the centre of the coil from the point O (Fig. 48),* and let $C^2 = A^2 + B^2$. Let x be the distance from O of any point Q on the axis. Maxwell shows that as long as x is small compared with C, the magnetic force at Q for unit current is $F = G_1 + 2\,G_2\,x + 3\,G_3\,x^2 + \ldots$ Hence, to find the big G's we determine by the aid of § 26, or otherwise, the magnetic force at Q, and expand it in *ascending* powers of x. We then equate the coefficients of the powers of x in the two series, and thus find G_1, G_2, &c. To find the little

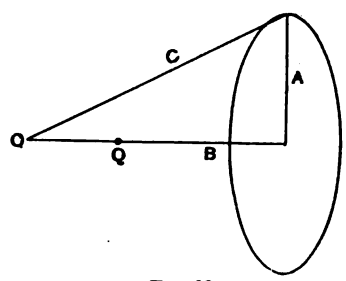

Fig. 48.

g's we proceed as follows:—Let b be distance of centre of the coil from O (Fig. 49), and let $c^2 = a^2 + b^2$. Maxwell shows that if Q′ is a point on the axis, and O Q′ $= x$, then, when x is large compared with c, $F' = 2\,g_1/x^3 + 3\,g_2/x^4 + 4\,g_3/x^5 + \ldots$ F′ being the magnetic force due to unit current. Expanding the expression obtained by § 26 in *descending* powers of x, and

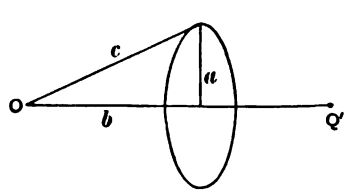

Fig. 49.

equating the coefficients of the powers of x in the two series, we obtain the values of g_1, g_2, &c. In this way we find

$$G_1 = 2\pi A^2/C^3,\quad G_2 = 3\pi A^2 B/C^5,\quad G_3 = 4\pi A^2 (B^2 - \tfrac{1}{4}A^2)/C^7,$$
$$G_4 = 5\pi A^2 B (B^2 - \tfrac{3}{4}A^2)/C^9,\quad g_1 = \pi a^2,\quad g_2 = 2\pi a^2 b,$$
$$g_3 = 3\pi a^2 (b^2 - \tfrac{1}{4}a^2),\quad g_4 = 4\pi a^2 b (b^2 - \tfrac{3}{4}a^2).$$

If we have a pair of fixed coils as in the Helmholtz arrangement we require to know the values of the big G's at the centre of the system. There are two cases to consider, since the current may circulate in the same or opposite directions in the two coils. We take first the case where they flow in the same direction.

It is clear that if G_1', G_2' . . . refer to one coil and G_1'', G_2'' . . . to the other, then $G_1 = G_1' + G_1''$ $G_2 = G_2' + G_2''$, and so on.

* The *axis* of a circle is a line through its centre at right angles to its plane.

* In Figs. 48 and 49 all the lines are *in* the plane of the paper, with the exception of the circles, which are supposed to be at right angles to that plane.

Digitized by Google

Thus if the two coils are exactly equal and placed at equal distances from O we have

$$G_1 = 4\pi A^2/C^3, \quad G_2 = 0, \quad G_3 = 8\pi A^2 (B^2 - \tfrac{1}{4} A^2)/C^7, \quad G_4 = 0,$$
$$G_5 = 12\pi A^2 (B^4 - \tfrac{3}{2} B^2 A^2 + \tfrac{1}{8} A^4)/C^{11},$$

since G_1, G_3 . . . are not affected when we change B to – B.

In a similar way if the currents flow in opposite directions in the two coils we must change the sign of G_1'', G_2'', &c., before addition. Thus we have in this case

$$G_1 = 0, \quad G_2 = 6\pi A^2 B/C^5, \quad G_3 = 0, \quad G_4 = 10\pi A^2 B (B^2 - \tfrac{3}{4} A^2)/C^9.$$

§ 55. **Application to the Electro-Dynamometer.**—Returning to this instrument, we see that when the origin O is taken at the centre of the suspended coil, since the current flows round the two coils in the same direction, G_2 G_4 G_6, &c., vanish. When the Helmholtz pattern is adopted for the fixed coils G_3 vanishes, since then B = A/2. Thus, the expression for the coefficient of mutual induction reduces to the following—$M = G_1 g_1 P_1(\theta) + G_5 g_5 P_5(\theta)$. Since the product $G_5 g_5$ is small compared with $G_5 g_5$, we need generally only retain the terms written above. Now, since ϕ is the angle of deflection of the suspended coil $\phi = \pi/2 - \theta$. When ϕ is small, so that $\theta = \pi/2$ nearly, $P_5(\theta) = \frac{15}{8} \cos\theta$, while $G_5 = -\frac{144}{625} G_1/A^4$, and for a single suspended coil placed at the centre, where $b = 0$, $g_5 = \frac{5}{8} a^4 g_1$. Thus very nearly

$$M = G_1 g_1 \sin\phi \{1 - 27\, a^4/100\, A^4\}.$$

The couple experienced by the suspended coil is

$$i^2 \frac{dM}{d\phi} = G_1 g_1 \cos\phi (1 - 27\, a^4/100\, A^4).$$

Hence we can correct our previous approximation by multiplying by the factor $1 - 27\, a^4/100\, A^4$.

The suspended coil is sometimes made in two halves, which are arranged in the Helmholtz fashion. In this case g_3 vanishes. The advantage gained by this construction is as follows:—On account of the finite space occupied by the windings on the large coil, G_3 does not completely vanish, but by making g_3 vanish, we get rid of the product $G_3 g_3$ entirely. The instrument at the Cavendish Laboratory which is figured in Maxwell, Vol. II., p. 339, is arranged in this way. By this arrangement g_5 becomes $-\frac{5}{16} g_1 a^4$, so that the correction depending upon g_5 is slightly greater than when the simpler pattern is adopted for the suspended coil.

§ 56. **Practical Example.**—As an example of the use of the electro-dynamometer in "absolute" measurements, we may quote the work of Mr. Dugald McKichan on "The Determination of the Number of Electrostatic Units in the Electromagnetic Unit" (*Phil. Trans.* Royal Soc., 1875). The research was carried on at Glasgow University.

Here the fixed coils conformed closely to the Helmholtz pattern, while the suspended system was a single coil. The mean radius of the large coils was about 16cm., and the mean radius of the small coil about 4·2 cm. The correction depending on $P_5(\theta)$ is just appreciable in this case, but no account was taken of it in the calculations; it amounts to about 1 part in 780 in the value of i^2. There were on the two large coils together 7,389 turns of wire. The value of g_1 which was found by comparison with the large coils, was about 195,000 sq. cm. The instrument was adapted for the measurement of very small currents, a deflection of one scale-division ($= \frac{1}{10}$ inch) at a distance of 446cm. from the mirror corresponding to a current of about ·00002 C.-G.-S. units or ·0002 amperes. Since the current is proportional to the square root of the deflection, it follows that the deflection of about 400 scale divisions, which was generally obtained, corresponded to about ·0004 C.-G.-S. units, or ·004 ampere. The suspended coil was not hung by a bifilar suspension, but by a single wire, the electrical connexions being completed by a fine wire coiled into the form of a spiral spring, and attached to the lowest part of the suspended coil. The experimenter considered that the deflection, θ, was so small that its square might be neglected compared with unity. The error introduced on this score only amounts to one part in about 3,000; and, under these circumstances, sin θ and θ may be considered identical. In order to diminish the differences in the readings which arise in consequence of the earth's action, magnets were arranged so as to neutralise the earth's magnetic field at the centre of the instrument as nearly as possible.

We have now said sufficient about the electro-dynamometer, and shall go on to consider with greater exactness than in § 48 the theory of the "current-weigher."

(To be continued.)

RADIATION OF ELECTRIC ENERGY.*

BY FRED. T. TROUTON.

(Concluded from page 281.)

In Fig. 3 is shown one of Prof. Hertz's original pattern radiators; is in principle the same as the one in Prof. Lodge's experiment. The square metal plates to right and left correspond to the outside and inside coating of the jar. It differs in the current alternating somewhat more rapidly. The time elapsing between each swing is about $\frac{1}{300,000,000}$th part of a second. That is to say, if the oscillations continued for one second, 30,000,000 would have taken place. In order to form some idea of the stupendous rapidity with which they succeed each other, I may mention that a clock ticking once every second would require to be kept going for 347 days (almost a year) before its pendulum would have performed the number of vibrations that would here take place in one second. As a matter of fact, only a dozen or so of these vibrations really occurs, so rapidly is the energy radiated, each one being less than the last, like the vibrations of a string of a musical instrument.

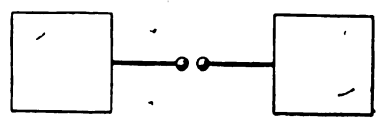

FIG. 3.—Form of Hertzian Radiator.

Just as in Prof. Lodge's experiment, a spark is produced in a receiver identical in form with the radiator, placed at some little distance away; but as this is small, it is often convenient, when wishing to exhibit to a number at once, to use a sensitive current detector with a spot of light in the usual fashion; for by its means, curious enough to say, we are able to see when the receiver is affected. The wires leading to the detector are connected one to either plate of the receiver.

Non-transparent objects, such as metal sheets, can cast shadows and stop their electric radiations just as they would with light. As a rule, things which stop light stop these radiations, and things which let light through let them through also. In this respect, and in many others, which we will refer to later, there is the greatest resemblance between the properties of light and of these electric radiations. Maxwell many years ago anticipated such, and suggested that light itself was but an electric radiation, with an extremely high rate of alternation. Amongst other reasons brought forward for supposing this was that the speed, calculated from purely theoretical considerations for electric radiations, agreed precisely with what had been found to be the speed of light—180,000 miles per second. It remained, however, for Prof. Hertz to put the matter beyond all doubt by measuring the speed by actual observation; and we will now endeavour to see how this was done, by employing a rope as an illustration.

Suppose one end of the rope fastened to the wall, the other held in the hand, when the unattached end of the rope is given a shake, a wave is observed to pass up along it; and if one watches closely one will see that when the wave reaches the fastened end another wave apparently starts, and travels back along the rope. That is to say, the wave is reflected at the end, and comes back to us. (Fig. 4).

* The conclusion of a course of lectures delivered in Inverness, December, 1891, under the auspices of the "Ettle's Trust."

Digitized by Google

By continuing to shake the free end at a uniform rate waves, consisting of a number of hills separated by hollows, can be sent travelling along the rope; each of these, of course, must be reflected at the fixed end, and ought thus to form a procession of waves passing back along the rope. But this is not as it will appear to us, for we must remember that what we actually see is the result on the rope of a continuous procession of waves going up to the end, as well as of those coming away after reflection.

The combined effect of these two processions of waves travelling in opposite directions, thus produced by reflection, is seen to be that there are a number of points along the rope, situated at equal distances apart, which remain at rest, and never go up to make a hill or go down to make a hollow. And if we think for a moment this is the only thing the rope could do; for each hill returning from the fixed reflecting end must at certain points meet the oncoming hollows, now the returning hill tends to raise the rope, while each oncoming hollow tends to move it downwards, the result is where they meet the rope has to remain at rest. Again, between these points the returning hill encounters an oncoming *hill*; and here, when this happens, the rope gets an increased swing up. It is in like fashion for two hollows, which are in truth but hills when viewed from the other side. In this way we see the rope is thrown into portions, which vibrate strongly, these portions of rope being separated by points which remain always at rest.

Now, the distance from one point of rest to the next is half the distance the waves travel in the time of one vibration, for it is obvious a returning hill is met on each occasion half way by an oncoming hollow; for they are both moving at the same rate and in opposite directions, so that, by measuring this distance, we can find the speed the waves travel at, provided we know the time taken for each vibration.

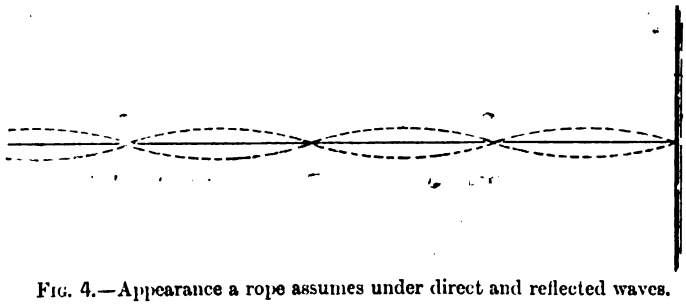

Fig. 4.—Appearance a rope assumes under direct and reflected waves.

It was after this fashion, then, that Prof. Hertz succeeded in determining the speed of electric waves. By means of a reflecting sheet of zinc the waves travelling in the opposite direction to the original ones were produced; and these at certain points destroy or neutralise each other's action, just as we have seen is the case with the waves on the rope.

In this way, then, by measuring the distance apart of these points, one is able to determine the speed these electric waves travel at, provided the time the current takes to alternate is known, and the way to ascertain this by calculation was shown long ago by Sir William Thomson.

Among some of the other points of resemblance between these electric rays and light, to which I alluded before, is (1) that these rays were found by Prof. Hertz to be bent to one side on passing through a prism, just as we know light to be by passing it through a glass prism. (2) Again, these electric rays are found not to be reflected by ordinary thin sheets of glass,* though thick sheets, or in that case, more properly speaking, walls of glass reflect strongly. This is quite in agreement with light for extremely thin sheets; for instance, soap bubbles, when just about to burst, reflect no light, as is well known; ordinary sheets of glass being equally thin compared to our long electric waves, as the thinnest soap bubble is to the minute waves of light.

Further, to make the likeness more complete, I may mention that when soap bubbles are viewed with mono-chromatic light (*i.e.*, light of one colour), as the sides of a bubble drain away and become thinner the bubble goes through stages of reflecting and of not reflecting the light, according to the thickness—that is to say, at a certain thickness there is reflection; at a little thinner than this there is none; at a little thinner again there is again reflection, and so on till the bubble bursts. In like manner walls—for such the thin sheets have to be in the case of these long electric waves—have been found to reflect or not to reflect according to their thickness after the same fashion.

Another, and perhaps a more striking resemblance, is that (3) both light and these electric waves refuse or allow themselves to be reflected obliquely from non-metallic surfaces, according to the direction they are vibrating in.

Without going further, we see there is abundant evidence to show the great resemblance between light and these electric waves. In fact, there can be no doubt but that they are in every way identical, excepting in so far that, in the case of light waves, the undulations succeed each other with exceeding rapidity, compared with the electric waves we have been dealing with.

We thus are brought to the conclusion that, could we only contrive an electric radiator after Prof. Hertz's plan, which would vibrate fast enough, and send out successive undulations at short enough intervals, we would have a source of illumination, for the radiation would affect our eyes, and be in every respect what we know light to be.

Many experimenters are at the present moment working at this problem from different directions, the great desideratum being the production of light without the simultaneous production of useless heat, which occurs in all the means we now employ for artificial illumination. Instances of the production of light without heat are to be found in the light emitted by many organisms, such as the glow-worm; and in the illumination afforded by certain substances after exposure to bright light, such are often put up in small tubes, and ornamental designs for the purposes of exhibition. After exposure to bright light they continue to glow for some time, although they remain quite cool.

Many of these substances also glow when placed in tubes exhausted of air, and an alternating electric current passed over them.

What we do here is apparently to give the molecules of these substances a great shake every now and then, they continuing to vibrate between each disturbance after their own fashion as little electric radiators, thus affording us light. Experiments lately made by Prof. Tesla, of America, seem to show that the more frequently they are disturbed the better. An ideal, of course, would be to give them a help each oscillation by a synchronous alternating current. Prof. Tesla has built an alternating dynamo, which afforded currents alternating 20,000 times a second; but this is far and away short of what would be required, if in truth such a thing is possible, as a circuit carrying a current alternating in periods comparable with that of light. The speed of rotation and the number of coils which can fit on a rotating disc seems nearly reached in his machine; but by combining the principle of the transformer with that of the dynamo, we could push the rate of alternation beyond these mechanical limits: for instance, by passing an alternating current through the field-magnets of an alternating dynamo instead of the usual continuous current.

We might suppose this done by having two machines on the same shaft, the first arranged as usual, while the field-magnets of the second derive their current from the armature of the first, and in such a way that when the armature coils and field coils are closest the current in the field coils should be zero. The current from the armature of the second machine would thus be of double the rate, for we have superimposed on the geometrical zero position of the armature coils which occur half way between two field coils, zero position situated *at* the field coils. The two machines might, of course, be combined, only in that case the field-magnets of our second machine rotate, and are in fact the armature coils of the first, while the second set of coils to form the second armature would remain at rest. Unfortunately, we cannot go on in the same fashion doubling the rate, only, indeed, adding subsidiary vibrations by further machines.

So far, the long electric waves, as distinguished from the short electric waves of light, are of a purely theoretic interest;

* As glass happens to absorb these long electric waves, it is not so suitable for making the experiment with as other dialectrics; but for convenience of expression is spoken of here.

but no doubt they will be turned by man to subserve useful purposes. The great difficulty which lies in the way is, that the radiation produced by the automatic method with intermittent supply of energy, the only one yet used, is necessarily insufficient in intensity to be powerful at considerable distances, owing to the vibrations dying rapidly out, like that of a violin string. So that until some other form of apparatus is invented, to be supplied continuously with energy, so as to produce a continuous vibration, and to which we can harness on a 50-H.P. engine, and get a really powerful beam of these electric rays, there can be no great advance hoped for. Such an arrangement is, perhaps, possible through the device of affording two alternate paths for a continuous current, each of these being interrupted by a spark gap, and the arrangements being such that either spark in turn was magnetically blown out by the action of the current as soon as it had started; a definite resonant period, by the attachment of a condenser, being imposed, after the fashion of an organ pipe.

There is little doubt but that a powerful beam of this sort would, unlike light, be unabsorbed by fog; so, looking into the future, one sees along our coasts the light-house giving way to the electric house, where electric rays are generated and sent out, to be received by suitable apparatus on the passing ships, with the incomparable advantage that at the most critical time—*in foggy weather*—the ship would continue to receive the guiding rays.

It had often been a matter of surprise that human beings, the highest in the scale, were unprovided with electric organs of some kind or other, while other creatures of more humble type were so endowed; for instance, the electric eel with its destructive powers. But that we have electric organs, and those of a most beneficent nature, is now known; for science now shows us that our eyes are but resonant receivers of the minute electric waves which constitute light.

A LIGHTNING STROKE AT PREETZ.

In the *Elektrotechnische Zeitschrift* for December 25, 1891, Prof. Leonhard Weber describes the results of his investigations with regard to a lightning discharge which occurred in the afternoon of August 22, 1891, at the little town of Preetz, near Kiel. The storm consisted of a single flash, which was concentrated upon the church, although its effects were also visible in other parts of the town.

The church was provided with a lightning conductor put up in accordance with the latest ideas. One conductor ran direct from the point of the rod to an earth plate sunk eight metres in the ground. Another ran along the ridge of the roof of the nave, terminating on the one hand at earth plate II. and on the other at earth plate III., being taken over the chapel to it. Line No. 1 was connected to the gas pipes, and line No. 2 to the water pipes; the two lines being also connected together. A third conductor connected the other extremity of the ridge with earth. As to the metal work inside the building the following precautions had been taken. Both clock and bell were connected to line No. 1, and two long iron T pieces which crossed the belfry were joined at one end to the same conductor. Four large iron bars which ran across the nave were connected with the two metal rain-water pipes, one of which was in connection with one of the earth wires.

The resistances of the various circuits were measured, and the majority were not more than one ohm; one circuit, however, gave 21·6 ohms. This arrangement of conductors would appear therefore to have been erected according to leading principles. The conductors were sufficiently large, consisting as they did of 9mm. copper wire. All the salient points of the edifice were protected; and the water and gas pipes, as well as the metallic parts of the building, were in good connection with the lightning rod, the earth of which was excellent. Only the metallic wires which secured the ornaments of the nave were insulated.

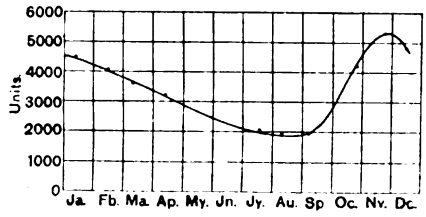
The following effects were visible. The silver tip of the lightning rod was partially melted, and the iron pipe surrounding the earthed portion of conductor No. 1 was melted for a quarter of its length, the mouth of the pipe being very markedly damaged. At the spot behind the organ where the two iron T's came into the interior of the church their extremities were much pitted. The ends of these iron T's were one metre away from the roof, which was also pitted along its entire length, and especially so in the vicinity of the iron bars traversing the nave. A discharge had therefore taken place between the metallic wires mentioned above and the iron. From this Prof. L. Weber concludes that the lightning would have had no effect if the two iron T's had been connected with iron bars crossing the nave. These long iron T's projected into the church like two gigantic branch conductors, being connected to the main conductor only at one end.

Prof. Weber concludes that the discharge must have been a slow one with a sudden increase of intensity: a rapid and oscillatory discharge being in his opinion out of the question by reason of the calorific effects observed, and a slow and steady discharge being equally so by reason of the injury done to low-resistance earth circuits. A slow discharge with a sudden increase of intensity would explain both the fusion of the silver tip and the lateral discharges. A second explication could be based on the fact that very often a discharge is not directed upon the large conducting masses of underground sheets of water or of gas or water pipes, but rather upon the damp soil surrounding a building. In the case under consideration the connection between the surrounding rail and the metallic portions of the building was mainly by the water pipes. There was, it is true, a metallic circuit running outside the water-piping to the belfry, and thence to the top of the conductor; but the shortest route was by the iron bars of the nave, the roof crossed in all directions by metallic wires, and the iron T's of the belfry; although it must be observed that there were gaps of 1 and 2 metres in this circuit.

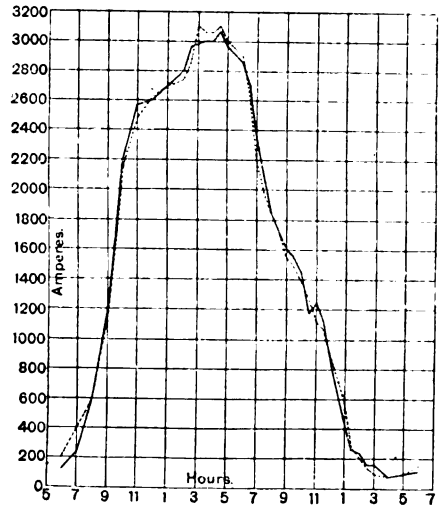
Whether we seek an explication of the effects observed in one or other of these ways, it is certain that if the number of conductors running to earth had been increased, the disruptive discharge within the church could have been prevented. Finally, it is to be remarked that the gas and water pipes were uninjured, which was to be expected. On the other hand, they would certainly have been destroyed if they had not been connected to the circuit of the lightning conductor.

SAMPLE LOAD CURVES OF THE ST. JAMES'S AND PALL MALL STATION.

We give below some load curves, which may be taken as typical of the demands made upon the St. James's Company's station for each month during the past year. The first diagram is deduced from the last twelve, and is typical of the *total* units generated in any one month of the year. The difference



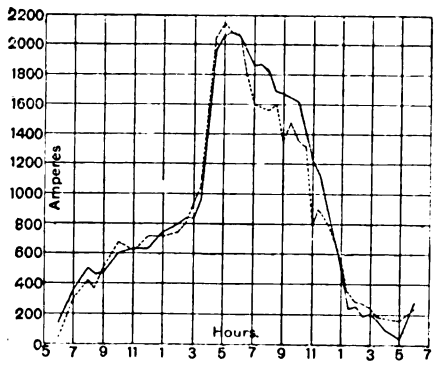
1891.—Curve typical of the monthly variations in demand.



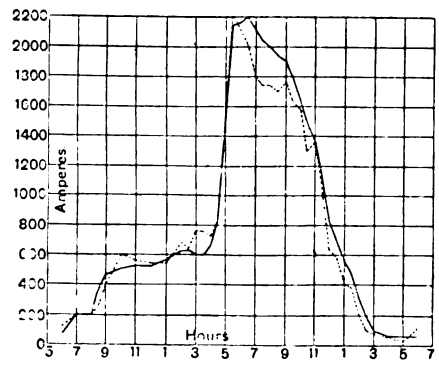
December 22nd.—Total units supplied, 7,942. (Deep Fog).

Digitized by Google

between the average demand in July and in November is very instructive; and in the case of the St. James's Company the additional lamps connected to the mains in the interval being insignificant, the November increase may be taken as due solely to climatic and meteorological conditions. The ample dimensions of the area enclosed by the second curve, which refers to Tuesday, December 22, 1891—a day of fog and darkness—may be contrasted with the last diagram of all, which shows a curve typical of the normal state of things in December. The full lines on the sample monthly curves show the current going out on one main, and the dotted lines give the current going out on the other main, so that the ordinates have to be added together to obtain the total output. The even balancing of the two circuits is worthy of notice.



January 12th.—Total units supplied, 4,514.



February 16th.—Total units supplied, 4,104.

THE NEW FRENCH CUSTOMS TARIFF.

The following extracts relating to electrical goods, from the New French Customs Tariff, which comes into definite operation on the 1st February next, may be of interest. In spite of careful search we have been unable to discover any reference to a tax on insulated cables, telephonic apparatus, switches, &c., although at one time the French electrical industry appeared to be demanding, all round, ultra protective duties, on the plea of restoring the commercial equilibrium. The London Chamber of Commerce inform us that the Minimum Tariff will apply to British products:—

Tariff No.	Article.	General tariff per 100 kilogrammes.	Minimum tariff per 100 kilogrammes.
		francs.	francs.
191	Graphite or Plumbago	Exempt.	
193	Bitumen	dito.	
200	Platinum and Gold—		
	(*a*) Ore	dito.	
	(*b*) Crude; in mass, bars, ingots, powder, broken up articles	10	10
	(*c*) *Thread, Sheet, or Wire.*—Fine drawn, simply laminated, in bars of at least 5mm. thickness, in sheets of at least 1mm. thickness, or as wire of at least 2mm. diameter	10	10
221	Copper—		
	(*a*) Ore	Exempt.	
	(*b*) *Pure or alloyed with Zinc or Tin*—		
	Crude; in mass, bars, pig, or sheet	dito.	
	Laminated, or beaten into bars or plates	13	10
	In wire of any dimension (polished or unpolished) other than gilded or silvered	13	10
224	Zinc—Sheet	4	4
238	Sulphuric Acid	Exempt.	
239	Lead Oxides—		
	(*a*) Minium	5	2
	(*b*) Litharge and other oxides	5	2
312	Carbons prepared for Electric Lighting	75	50
319	Glass Insulators	6	4.5
361	Incandescent Electric Lamps, capped (*munies de leur monture*)	400	350
361 (bis.)	Incandescent Electric Lamps, uncapped	800	700
475	Tubes and Conduits of Bitumened Paper	1.25	1
504	Large Clockwork. Clock movements, ditto telegraph instruments, counters, and every so-called clockwork movement, except that of a watch, complete or incomplete, with or without motor systems	100	75
505	Electricity Counters	100	75
510	Stationary Steam Engines, Heat, Gas, Petroleum, Hot Air, and Compressed Air Engines—		
	250 kilogrammes and more	18	12
	Less than 250 kilogrammes	30	20
511	Semi-Portable Steam Engines	17	13
524	Dynamo-Electric Machines—		
	1,000 kilogrammes and upwards	30	20
	50 kilogrammes to 1,000 kilogrammes	45	30
	10 kilogrammes up to and less than 50 kilogrammes	100	80
526	Steam Boilers, iron or steel, simple or furnished with feed water heaters, internal furnaces, but without tubes	12	9
526 (bis.)	Steam Boilers, iron or steel, tubular or semi-tubular, that is to say, having iron, steel, copper, or brass tubes	18	14
536	Armatures of Dynamo Electric Machines and separate parts, such as solid or hollow metal bobbins wound with insulated copper wire; worked copper pieces, weighing less than 1 kilogramme, numbered and marked, mounted or unmounted; intended for electric apparatus and arc lamps	100	75
576	Lead Piping, and all other kinds of lead work	4	3
576 (bis.)	Electric Accumulators	17	13
578	Worked Zinc, ordinary, united or stamped	12	8
620	India Rubber and Gutta Percha Materials—		
	(*a*) India rubber sheet; pure unvulcanised and vulcanised rubber thread	60	40
	(*b*) Belts, tubes, valves, and other India rubber and gutta percha work, pure or mixed, soft or hard, combined or uncombined with cloth or other material	90	70
634	Optical, Mathematical, Astronomical, and other Instruments of Precision	Exempt.	

APPLICATION OF ELECTRICITY TO THE DRILLING OF METALS.*

After some introductory remarks, the author went on to describe what had come within his own experience in the use of electro-motors in the drilling of metals. His firm used the size known as an inch driller, which was self-contained—that was to say, the electro-motor, wheel-gearing, drill-spindle, and electro-magnet were all carried on one framing; and the total weight of the machine and its framing was 314lb.; so that it was not too heavy to move, even by hand labour, from place to place. On the armature spindle of the motor there was a pinion-wheel, which geared with a spur-wheel on the second-motion shaft, another pinion which geared with a spur-wheel keyed on the drill-spindle. The motor and electrical connections were contained within a sheet-iron casing, and the pinions and spur-wheels were in a cast-iron box. In the machines used by the author's firm the motor spindle makes, on an average, 2,000 revolutions per minute, and the drill-spindle makes an average number of 125 revolutions per minute. This gives a ratio in the gearing of 1 to 16. The machine would be improved if the average number of revolutions of the motor were increased, as there would then be a larger margin to allow for differences in the sizes of the holes bored, variations in the electric current, and differences in the amount of feed put on the drill. The holding power of the electro-magnet is 1,650lb., which should also be increased; and the soft iron cores of the magnet are each 2⅝in. diameter, but they could be made larger, without in any way interfering with the handiness of the machines. At present it is possible, by screwing on a heavy feed on the drill, to slacken the grip of the electro-magnet on the work, and feeding had therefore to be done with some care so as to avoid such taking place. There was a difficulty in getting any reliable data as to the amount of pressure required to be exerted endwise on a drill when boring holes in metals. From some experiments made by a Glasgow firm, it was found that 916lb. pressure was required in boring mild steel with a drill ⅛in. diameter (the drill being flat on the sides); and 616lb. pressure was required with a drill of the same diameter, but having the edges feathered. In each case the drills were making 136 revolutions per minute, and had a feed of 312 turns per inch. Whatever might be the value of the results of the experiments referred to, it was found that a larger holding power was necessary in the magnet of a portable drilling machine, especially when boring upwards, in which case the machine had to support its own weight in addition to resisting the pressure on the point of the drill. It was also found in actual working that the best results were got by keeping the speed of the machine as high as possible and using a fine feed.

The main cables for the dynamo were led overhead through the boiler yard and sheds; and along the columns of the main building coupling pieces are placed on the cables, so that the current may be taken off and led by means of branch wires to the drilling machines wherever they may be employed. The current was from 12 to 14 amperes, and the voltage was 100. That was a comparatively safe current to employ, and in ordinary circumstances no one ran any danger in handling the machines. By means of a switch the man in charge could make the connection which threw the current into the electro-magnet, and fixed the motor in its required place against the object to be drilled, whether a separate plate or the side of a ship, or a boiler, or a girder. By a further movement of the switch he threw the current into the electro-motor working the drill; and by a handle at the back he fed the drill forward to the plate, and also while it was boring.

With a current of 12 amperes and a voltage of 100, the machine in ordinary working could bore a hole 1¼in. diameter through an iron plate 1in. thick, in an average time of two minutes, or a hole 1in. diameter through ¾in. steel plates in one minute 15 seconds. With an increase of current to 14 amperes, 1½in. holes were bored through 1in. iron plates in one and a-half minutes. Such tools as had been spoken of might not, in the meantime, be capable of doing the work any cheaper or any quicker than by present methods—although in many cases, if not in all, they would hold their own both for cheapness and for quickness in the execution. The great advantage gained in using them lay in the fact that they were portable; they could be taken to the mark wherever it might be, and they could be set on to attack the largest masses. They were specially useful for boring holes in out-of-the-way places, or within the areas of large plates, where no other form of machine driven either by power or by hand could, perhaps, be so readily applied. The electric drill was said to be specially valuable for boring the holes for the steam mountings and for other odd jobs about a boiler. A short time since the author noticed that a man bored a 2in. hole force feed check valve

* Abstract of Paper communicated to the Graduates' Section of the Institution of Engineers and Shipbuilders, Glasgow, by Sinclair Couper, Engineer.

Digitized by Google

through a ¾-in. plate on the circumference of a boiler in four minutes, and he bored five holes for bolts in one minute each.

The author subsequently mentioned many interesting facts in connection with varied methods of working, and gave details as to comparative cost, all of which went to show that there were great advantages attending the application of electric energy for drilling metals, and similar purposes, and his decided conviction was that there was a great future for it in many directions.

MODERN APPLICATIONS OF ELECTRICITY TO METALLURGY.*

BY G. C. V. HOLMES.

During the last few years the application of electricity to lighting and to motive power had, said the author, received the greatest attention from the engineering profession, but comparatively little notice had been taken of the equally important application of this force to metallurgy and the manufacture of metal goods. At the present moment, however, the manufacture of copper goods by electrical methods was beginning to excite considerable attention in the engineering world. The author next proceeded to go into the elementary principles of electro-chemistry at some length, and then came to the practice.

Copper-Refining Apparatus.—The practical apparatus required to refine rough copper electrolytically was, he said, of the simplest kind. A boiler, steam-engine, and dynamo were, of course, indispensable. The electrical output was, of course, determined by the surface of anodes, which it was intended to expose in any one tank or bath, the usual allowance being a current of between 4 and 5 amperes per square foot of surface. The electromotive force of the current depended upon the number of tanks which it was intended to work in series, and on the average of the combined resistances per tank. With a well-arranged plant, the difference of potential between the anode and the cathode of each tank should be considerably less than half a volt. The tanks were generally made of wood, and measured about 3ft. in each direction. They were rendered acid-proof by being lined with lead, or some composition into which pitch enters largely. It was of the utmost importance that the tanks should be perfectly acid-proof, not only in order to avoid loss of the electrolyte by leakage, but also to ensure insulation. On the tops of the sides of the tanks at front and back were placed strips of copper, which served as conductors, and which are alternately connected. The anodes were square plates of cast rough copper. The cathodes were sheets of thin copper. Several anodes and cathodes were hung parallel to each other in each tank, and when a sufficient thickness of electrolytic copper was deposited on the cathodes they were removed from the bath, and the deposited layer was easily split away from the original cathode, which remained intact and ready for fresh use. The thickness of the deposited copper on the cathode was a matter principally affected by the capital at the disposal of the firm for locking up in raw material. The electrolyte was formed by dissolving 2lb. of sulphate of copper to each gallon of water, and adding 8oz. of concentrated sulphuric acid. The aim of the refiner was to procure a supply of rough copper containing a good proportion of gold and silver. Many brands of copper were exceedingly rich in the precious metals, and it was usual to allow a certain proportion of the assay value free to customers.

Cost of the Process.—The cost of the operation of refining copper was determined mainly by the difference of potential between the anodes and kathodes in each tank. The lower the latter, of course the less cost. It had been shown that with a pure anode, only sufficient electromotive force had to be provided to overcome the ordinary resistances, while with an impure anode an additional difference in potential was required to overcome the back electromotive force due to the accumulation of oxides on the anode, and a portion of the energy of the current was, of course, absorbed in oxydising the foreign metals present. It so happened that while it was easy by the old methods to refine rough copper up to, say, 98 per cent., it was very difficult by these methods to get it still purer. By the electrolytic methods on the contrary it was much easier to take the last impurities out than it was to refine a really rough copper. Thus the two methods might be said to be complementary to each other, and in practice it was desirable to bring the metal by the older, methods up to such a state that only about 2 to 3 per cent. of impurities remained in it. The principal resistance was in the electrolyte itself. This resistance could be diminished by reducing the length of liquid which the current had to traverse and by increasing its cross section, that was to say by bringing anode and cathode as close together as was found to be practicable and by exposing as large an area as possible.

It had been stated that in practice the difference of potential between terminals of any one tank was between one-half and one-quarter of a volt. Taking, however, the figure of two-thirds of a volt as a standard and briefly examining the cost of producing the current, at a consumption of 2·24lb. of coal per I.H.P. per hour, one ton of coal should give exactly 1,000 I.H.P. for an hour. Assuming the combined efficiency of engine and dynamo to be 75 per cent., a figure well within the limits of the best practice, the above engine-power should give us 750 electrical horse-power, or $750 \times 746 = 559{,}500$—watt-hours. Supposing, for the sake of simplicity, that the whole of the work was done in one huge tank, the conditions of which allow the current to be passed through with a difference of potential of two-thirds of a volt; there would then be a current of $559{,}500 \times \frac{2}{3} = 839{,}250$ amperes for an hour. A current of one ampere for a second could deposit 0·0003307 grammes of copper; therefore, the amount deposited by the same rate of current in an hour $= 0{\cdot}0003307 \times 3600 = 1{\cdot}19052$ grammes, and, therefore, the current of 839,250 ampere-hours can deposit $839{,}250 \times 1{\cdot}19052 = 999{,}140$ grammes, or almost exactly one ton of copper could be deposited by the consumption of one ton of coal under the assumed conditions. Of course, for the purposes of the calculation, it would have done equally well to have taken the conditions which obtain in the actual process, namely, a much higher E.M.F. and a correspondingly reduced current. Thus, if an E.M.F. of 100 volts had been selected, a corresponding current of 5,595 ampere-hours would have been taken, and while the copper deposited in each tank would have been $\frac{1}{179}$th of what it was in the first case, the E.M.F. would be sufficient to pass the current through $100 \times \frac{2}{3} = 150$ tanks instead of one.

To the cost of fuel necessary for producing the current had to be added that of labour, maintenance, stores, and that of refining copper matte, or rough copper, up to the standard pitch of purity, and also that of casting the anodes. The actual cost of producing a ton of pure electrolytic copper varied also somewhat with the design of the plant and the care that was spent in maintaining it. If the current was allowed to run to earth, if conductors of scant area and if dirty contacts were used, if the electrolyte was not maintained in proper condition, if very impure anodes were employed, and if the current passed through the tanks was so dense that a high electromotive was necessary, the cost of electro refining copper might easily be made ruinously expensive. But if the conditions were made and maintained favourable, as they could be with moderate care, the cost should not exceed from £3. 10s. to £4 per ton, and had in some instances worked out much lower. If due care was exercised in the selection of the brand of copper to be refined, this cost might easily be more than covered by the value of the gold and silver recovered from the sludge in the bottom of the tanks.

Treatment for Rendering the Deposited Copper Suitable for General Use.—The copper deposited in electrolytic refineries, though chemically pure, was of a crystalline character, and possessed but little cohesive strength. It was, therefore, in its deposited condition, quite unsuitable for the manufacture of goods, and was, in fact, only used for the manufacture of high-conductivity wire for electric purposes; and before being drawn into wire it had to be melted, cast into ingots, forged, rolled, and cut into strips. If the copper could be deposited in a tough, dense, and reguline condition at the same time that it was being refined, a great saving of expense would result.

The remainder of the Paper was devoted to the details of the Elmore process.

One of the great advantages secured by the use of the burnisher over and above the superior quality of the metal obtained is that the current density per square foot of kathode may be from three to four times that made use of in electro-refining, or in ordinary electro-plating. A current of 20 amperes per square foot is commonly made use of, and even 28 amperes have occasionally been employed with perfect success.

* Abstract of a Paper read before the Junior Engineering Society, January 15, 1892.

Electrolytic Gas Experiments.—An interesting experiment has been lately made by M. Chabry, of the Société de Biologie, with regard to the pressure which can be produced by electrolytic generation of gas in a closed space. While the highest pressure before realised in this way was 6,570lbs. to the square inch (447 atmospheres, Gassiot), M. Chabry has succeeded in getting as high as 12,000 or 18,000lbs. to the square inch; and the experiment was broken off merely because the manometer cracked (without explosion). The electrolysed liquid was a 25 per cent. soda solution. Both electrodes were of iron; one was the hollow sphere in which the gas was collected, the other an inner concentric tube. The current employed was 1½ amperes, and was very constant during the experiment, which was merely one preliminary to a research in which very high pressures were desired.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).

The following report and accounts, being the first which we have had from a statutory electricity supply company covering a period of twelve months, and relating to a central station working under settled and generally favourable economic conditions, we have printed in greater detail than is our usual custom. The meeting is to be held at St. James's Hall Restaurant, Piccadilly, London, W., on Tuesday next, January 26th, at three p.m. :—

Report.

The Directors in submitting their annual report for 1891, with accounts as certified by the Company's auditors, congratulate the shareholders on the satisfactory progress made by the Company during the past year. Early in 1891 the capital of the Company was increased from £100,000 to £200,000 by special resolution of the shareholders creating 20,000 Seven per Cent. Preference Shares of £5 each. Of these shares 10,000 were issued to the shareholders at par, and fully subscribed for by them in March. The balance of 10,000 shares was issued in December last at 30s. per share premium, and duly allotted to the shareholders. This last issue of shares placed £15,000 at the disposal of the Directors as a capital reserve fund. The £15,000 has since been invested in Two and a-Half per Cent. Annuities, and is shown in the accounts annexed hereto.

The attention of the Directors has been largely directed during the year to the purchase of land for, and the erection of, a northern station. Owing to the congested condition of the parish and the extreme scarcity of available ground this proved to be a difficult matter. The Directors, however, are pleased to be able to report that they have secured a suitable freehold site in Carnaby-street, Regent-street, and have entered into a contract for the erection of the building on designs prepared by Mr. C. Stanley Peach, F.R.I.B.A. A considerable portion of the machinery and boilers required for this station have already been constructed, and it is hoped that during the summer of this year the station will be finished and in working order. There are certain compulsory mains which have to be laid in the parish before August next. These, with other mains which the Board deem necessary to complete the system, will be proceeded with without loss of time, and there seems every reasonable probability of the whole of the work being completed without any further capital being required.

It may be of interest to the shareholders to know that the two stations will be connected by a grand trunk main, about half of which is already completed and laid. This will be a means of enabling the northern station to support the southern in case of necessity, and *vice versâ*.

The system adopted by the Company has worked thoroughly well during the whole of the year, and the Directors are satisfied that it is the best that could be selected having regard to present knowledge. The experience gained at the Company's works enables the Company's officials to make improvements from time to time, and no precaution is neglected to maintain the excellent results hitherto obtained.

The net earnings of the Company during the past year have amounted to £10,395. 12s. 5d. Of this sum, £3,610. 6s. 4d. was distributed in July last in payment of an interim dividend at the rate of 7 per cent. per annum for the half-year ended June 30, 1891, on the ordinary shares, and on the instalments paid on the first issue of preference shares. The balance of £6,785. 6s. 1d., added to £315. 12s. 9d. (the undivided profit from last year's account), leaves £7,100. 18s. 10d. now to be dealt with.

The Directors propose to divide this amount as follows, viz. : –

(*a*) By payment of a dividend at the rate of 7 per cent. per annum calculated on the instalments paid on the first issue of 10,000 preference shares for the second half of the year	£1,333 6 8	
(*b*) By payment of a dividend at the rate of 10 per cent. per annum for the second half-year on the ordinary shares, making, with the interim dividend paid in July last, a total distribution of 8½ per cent. for the year	4,670 0 0	
(*c*) By paying a dividend of £10 15s. per share on the founders' shares	1,075 0 0	
(*d*) Amount to be carried forward to ordinary shareholders' undivided profit account	6 2 6	
(*e*) Amount to be carried forward to founders' undivided profit account	16 9 8	
	£7,100 18 10	

The Directors have carried £1,000 to "Redemption Account" to commence a fund, to accumulate by annual additions, to represent loss of capital at the expiration of the term covered by the Provisional Order. The Directors are advised that the amounts provided in the accounts for depreciation are sufficient and ample for all purposes.

Two of the Directors, namely, Messrs. Egerton H. Clarke and H. Woodburn Kirby, retire under Clause 79 of the Articles of Association, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths and Co., also retire, and, being eligible, offer themselves for re-election.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 8, 1892.

The Edison General Electric Company.—The topic of the hour is the coming annual meeting of the Edison General Electric Company. It was to have been held to-day, but, for some reason as yet not made public, has been postponed to an unknown date. The facts are kept hidden in the closest manner, so that very few, even among those high in the councils of the Edison Company, know what the delay means. Meanwhile there are as many opinions as men about the business that will be transacted at this meeting. It may be trivial, dealing only with minor matters, but the general opinion is that the results will be of far-reaching importance. It is understood that the present management is likely to go out, in part at least, probably almost as a whole. Whether in going Mr. Villard, the present president of the Company, will take Mr. Edison with him or not is a question as yet unsolved. Certain it is that Drexel, Morgan and Co. hold the key to the situation, probably controlling a majority of all the stock, in spite of Mr. Edison's large personal interest. If the new management promised to be inimical to Edison he might either make peace with them or leave with Villard; in the latter event, it is hinted that a new electrical organisation would take the field, based, perhaps, on the old North American Company, together with some others that Villard has been organising. It may be that the present delay in the annual meeting is due to interests connected with this organisation. Nothing has as yet leaked out, as is shown by the stability of the North-American stock and also of the Edison stock itself.

The Westinghouse Company.—The reorganisation of the Westinghouse Company seems to have been attended with considerable success, and that Company is apparently now engaged in a still hunt for business that is proving reasonably successful. Very little is said, but a considerable amount of work is done at the factory.

A Postal Telegraph System.—The annual report of the Postmaster-General recently published contains a strong plea for a postal telegraph system, a subject that is likely to be largely before the public during the next few years. It is earnestly desired by the Post Office authorities, but is looked at askance by the public in general. The Postmaster-General also suggests, what is much more practicable, a moderate use of a public telephone service by the Post Office department.

The Chicago Exhibition.—Work in connection with the Electric Section of the World's Fair is steadily progressing. The official situation there is particularly unfortunate, as the chief architect, Mr. Burnham, is now at loggerheads with the head of every department and with the Director-General. It is becoming a question whether the Exhibition will be Burnham's Fair or the World's Columbian Exposition. Mr. Barrett, of the Electrical Section, is doing everything in his power to put his department into good working order; but has encountered considerable opposition from the architect, who desires, for reasons best known to himself, to control the lighting problem personally.

The Proposed Electrical Congress.—The unfortunate difficulty between Prof. Elisha Gray, who was placed by the Government at the head of the Electrical Congress and the American Institute of Electrical Engineers, is apparently now at an end; Prof. Gray having seen the advisability of acceding to the propositions of the Institute.

Electric Traction in Brooklyn.—Something of a sensation has been created by the Mayor of Brooklyn vetoing the ordinance granted by the aldermen for the change in motive power from horses to electricity. It is probable that the hindrance will be but temporary.

CORRESPONDENCE.

OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to the paragraph which appears in your issue of the 8th inst., and to the letter from the Board of Trade on this subject which you publish, the fact that the memorial to the Board of Trade has been signed by a very large number of representative men in the industry points to the general feeling of anxiety which was felt that the Board of Trade intended to disallow all overhead wires for electric lighting. It will, therefore, no doubt be a matter of satisfaction to all who are interested in the electrical industry that the Board of Trade now state officially that "they have not laid down any absolute rule that overhead wires shall in no case be employed," although their statement "that they will be prepared to authorise the use of such wires in any case in which they are satisfied that the interests of the public require it" cannot be regarded as altogether a satisfactory position in which to leave the question.

The Memorial above referred to shows that electrical contractors have no wish to erect overhead wires otherwise than in accordance with regulations which the Board of Trade may prescribe in the interests of the public; and what the industry was afraid of was that the Board of Trade had laid down the principle that no overhead wires for electric lighting purposes should be used as a permanent arrangement. That such a misapprehension has arisen is perhaps excusable after the receipt by Messrs. Crompton and Co. of the letter from the Board of Trade, of which I enclose a copy.—I am, Sir, &c.,

St. George's Square, S.W. S. FLOOD PAGE.

[COPY.]

Ass'tant Secretary, Board of Trade,
(Railway Department), London, S.W.

CHELMSFORD ELECTRIC LIGHTING LICENSE, 1890.

SIR: With reference to your letter of the 23th ultimo, containing a description of the system of supply proposed to be used for the purposes of the above-mentioned License, I am directed by the Board of Trade to inform you that they are unable to approve of any system in which overhead wires are used as a permanent arrangement, and that they would not be prepared to give even a temporary approval to a system in which such wires were used unless they were erected in strict accordance with the regulations of this department.—I am, Sir, your obedient servant,

R. D. HERRINGTON.

DOES ELECTRICITY EXIST?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: As I have always taught that electricity has no real existence as a substance, or quasi-material fluid, or ether, of course your expressed disposition to that view is welcome; but still it may be questioned whether the "coulomb" is likely to

Digitized by Google

disappear from our growing list of units. To use your "American thinker's" phrase, though electricity is not an "is-ness possessed of somewhat-ness," it may be that it is a somewhat-ness manifested by an is-ness. That is my own view, and it follows that the is-ness will be a "quantity" involving the coulomb conception; while the somewhat-ness is represented by "potential" or stress force.

The misfortune is that the coulomb is not a quantity at all in any ordinary sense; it is itself a measure of energy in reality, as its very dimensions show; $L^{\frac{3}{2}} M^{\frac{1}{2}} T^{-1}$ or $M^{\frac{1}{2}} L^{\frac{1}{2}}$ do not represent an analogue of mass or quantity, yet the exact analogue does exist, obscured by our conventional system. The unit of electric quantity—the is-ness—is simply the unit of chemical structure of matter, the equivalent; while the "somewhat-ness" is manifested by it in the form of energy, which I christened "voltance" some while ago in these pages, the chemical form of potential.

Now, I want to question a scientific dogma, viz., that "heat *is* energy," as you say in your Note, p. 214. There has always been in my mind a dissatisfaction with the discrepancy in our ideas about heat and electricity, and I have just traced out the cause in the complete acceptance of the neat phrase, "Heat is a mode of motion," and the overlooking the fact that it is a motion of a "thing;" we treat it as a mere "somewhat-ness," and forget the "is-ness." As a simple natural truth, heat, electricity, and mechanical motion (such as the fall of a weight) have analogies (identities in principle), far more complete than Dr. Gerald Molloy sets out, p. 236.

In all we have exactly the same two elements: A, a material quantity; B, an energy exerted. In electricity we have for A the *equivalent of matter*, and for B the fall of potential, the expenditure of energy. In heat we have the *atom of matter* for A, and the fall of temperature, the transfer of energy, for B. In hydraulics we have the mere *mass of matter*, say a pound as unit for A, and, again, the loss of pressure, energy expended, for B. I may here refer to the suggestion that a "pound" is a measure of energy; as in so many cases that is a truth which hides a fallacy. When we look beyond the surface we must see that we have no measure whatever of anything except energy. Mass itself is only known as energy. We call it the measure of the absolute quantity of matter, but all we know about that is that it exercises a measurable force upon other masses. An atom of hydrogen is a mass of 1, an atom of silver is a mass of 108. Are these measures of "quantity of matter?" Who can say? All we know is that as regards the force of gravitation the atoms manifest these forces; but then as regards electricity they are equal, and as regards heat they are equal. Again, 108 of silver and 28 of iron are equivalent as electrical or chemical masses, but not as regards heat, which takes 56 of iron to equal 108 of silver.

Mr. Molloy, asking for the relations, says "the energy of the electric current resembles the energy of falling water, but does not resemble the energy of heat;" and so everyone would probably say, and say wrongly, as I probably should have said myself till lately. The reason of the error is that heat is readily treated mathematically and mechanically; it is only the chemist who has anything at all to do (and he very little more than as a fact of little practical influence) with the relation of heat to the atomic structures of matter. Therefore it is that in the mathematical and mechanical treatment, alike of heat, which can be treated wholly apart from its links to material structure, and of electricity, which can be so divorced, except in the study of electrolysis, the fundamental fact, the relation of energy to matter, is wholly overlooked, and mere symbols and conventions have shut our eyes to the plain teachings of nature.—Yours, &c., JOHN T. SPRAGUE.

$d\,M/d\,x$.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Myself, and I am sure many other non-mathematical readers, will feel obliged to Mr. Searle if he kindly shows how the numerical values of $d\,M/d\,x$, given in the table on page 251 of your issue of the 8th inst., are calculated.—Yours, &c.,

K. W. R.

PARSONS' STEAM TURBINES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: We were interested in Prof. Ewing's report on the above. Some years ago we put up a large resistance (40 ohms) of *very* open iron wire spirals, for the purpose of testing alternating-current dynamos. From careful experiments we found that the current passing, as measured by a Siemens electro-dynamometer, multiplied by the E.M.F. measured by a Cardew voltmeter, did not represent the electrical horse-power being given out. Indicator diagrams taken from engine showed that less horse-power was indicated in the cylinders than that in the external circuit, calculated as above.—Yours, &c.,

THE ELECTRIC CONSTRUCTION CORPORATION, LIMITED.
T. PARKER,
January 19, 1892. Chief Engineer and Head Manager.

STEAM-ENGINE ECONOMY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reference to the letter of Messrs. Willans and Robinson in your columns of last week, we would wish to state that it was not our intention to challenge record runs, and, therefore, in the tests made by Prof. Ewing no arrangements were made conducive to exceptionally high economies: these are the use of very high boiler pressure, and a separator or other means for obtaining very dry steam.

In the present tests the pressure at the engine never exceeded 75lb., and the steam was not dried.

It would be interesting to know with what steam pressure and engine Mr. Willans obtained the results stated by him at the meeting of the Institute of Civil Engineers last spring, for we are unable to find any mention of these two important factors in the proceedings of the Institute.—Yours, &c.,

C. A. PARSONS AND CO.

Heaton Works, Newcastle on-Tyne.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

NOW READY.—"THE ELECTRICIAN" PRIMERS (38 in all. Vol. I., 20; Vol. II., 18), in two volumes. Price per volume 2s. paper covers, 2s. 6d. cloth; post free, 2s. 2d. and 2s. 9d. respectively. Single copies, 3d.; post free, 3½d. Prospectus on application to the Publisher.

TENDERS INVITED.—The Public Lighting Committee of Waterford invite tenders for the public lighting of part of the city at present lighted by electricity, and also in the alternative, for the public lighting of the entire city, either by gas or electricity, for periods of two, five, or ten years, from September 1, 1892. All information can be obtained at the office of Mr. M. J. Fleming, borough surveyor, The Mall, Waterford; and tenders are to be sent to Mr. Joseph W. Howard, town clerk, by February 1st. Further particulars appear in our advertisement columns.

——— Tenders are invited for the lighting by electricity of the rooms which formerly constituted the kitchens at the Castle Museum, Nottingham, and should be sent to Mr. Geo. Johnson, town clerk.

TENDERS RECEIVED.—At the meeting of the Chiswick Local Board on Wednesday, the following tenders for the erection and maintenance of fire alarm posts, calls, &c, were opened:—Roxburgh and Co., with telephones, £330, without £290; Messrs. Blenheim and Co., with, £379; Messrs. Spagnoletti and Crookes, with, £415, without, £365; Mr. F. E. Stuart, with, £438. 17s., without, £368. 17s.; and the Home Telephone Company, with, £300, without, £265. It was decided that Dr. Diplock, captain of the fire brigade, should consult with the surveyor on the tenders, and report to the Board.

SIMPLEX ELECTRICAL SYNDICATE, LIMITED (IN LIQUIDATION).—A meeting of the shareholders is to be held at 4, Hercules-passage, Threadneedle-street, London, E.C., on February 16th, at 3, to receive an account of the winding-up.

MESSRS. LAING, WHARTON AND DOWN.—This firm notify us that the recent removal of the offices of the Laing, Wharton and Down

Digitized by Google

Construction Syndicate to 38, Parliament-street, Westminster, London, S.W., which has taken place owing to the increase of both businesses, in no way alters the address of the old established firm of Messrs. Laing, Wharton and Down, whose address is still 82A, New Bond-street, London, W., with branch and City offices at 17, Gracechurch-street, London, E.C.

THE PAST YEAR'S WORK.—Messrs. Priestman Brothers (Limited) report that successful progress has been made by the firm during 1891 in the introduction of the Priestman oil engine. The firm inform us that hundreds of these engines are now in daily use, and that during the past year, amongst many others, orders have been received from the New South Wales, Spanish, and Norwegian Governments, the Elder Brethren of the Trinity Honse, the Northern Lighthouse Board, Messrs. Bolckow, Vaughan, and Co., Palmer's Shipbuilding and Iron Company (Limited), Bell Brothers (Limited), and other public bodies and companies, both at home and abroad; and in addition to these important orders, several repeats have been received, included amongst which are the Norwegian Government for two 7 H.P. engines, the Northern Lighthouse Board for six engines, Messrs. Bell Brothers for five engines, and Volkart and Co. for three engines. The marine type of the Priestman oil engine has now been perfected, and orders have already been received for these engines. Amongst the uses to which this engine has been adopted during the past year may be mentioned electric lighting, hauling, pumping, &c. From the above it will be seen that the Priestman oil engine has demonstrated its usefulness, and it may fairly be said to be in competition with steam and gas as a motor.

——— We have received from the Mutual Telephone Company some particulars of the progress made during the past year, the chief point of interest in which is the fact that the Company has now (January, 1892) between 900 and 1,000 subscribers on their system. Three call boxes on the Company's boards at the Royal Exchange, Manchester, will be opened at the end of January. Subscribers to the Company's exchanges will be entitled to use these boards for the purpose of speaking within a radius of six miles without charge on producing evidence of identification. An exchange is to be opened in Bolton shortly, and trunk-line communication on the metallic-circuit system is to be established with Manchester, and it is also contemplated to open an exchange at Farnworth.

ST. PETERSBURG ELECTRICAL EXHIBITION.—On January 14th a series of trials took place of the motors, &c., exhibited at the Electrical Exhibition at St. Petersburg, which, we learn, were a great success. A committee has been organised consisting of engineers, technological specialists, and officers, for the purpose of explaining and demonstrating the use of the chief exhibits to the Russian public. St. Petersburg has been connected with Gatchino, the Emperor's summer residence, by telephone, as has also Pskov, distant about 170 miles. Much interest is taken in the Exhibition, which promises to be very successful.

TOOL BOXES FOR ELECTIC LIGHT FITTERS.—These tool boxes are made by Messrs. Kücke and Co., of Elberfeld, and are sold in this country by Messrs. O. Berend and Co. The box measures externally about 30in. × 19½in. × 15½in. high; it is made of tough wood, fitted with strong handles, and strengthened at the edges all round with strong metal mounts. To take the strain off the lock two hasps are provided, with castors let into the bottom. The tools are held in place partly by leather loops and partly by steel spring-hooks (which can be folded back), and are arranged in the lid and at the sides of the box, as well as on six moveable trays, folding down horizontally, the arrangement being such as to allow of inspecting at a glance the whole contents of the box, and enable the fitter to place every tool in such a position as to enable him to place his hand on any desired tool in an instant, and to remove it readily and without any obstruction. The central compartment, which, by means of a false bottom made to lift out, is divided into two halves, serves in its upper part for storing the fitter's working clothes, while the lower division contains a tackle of pulleys and various wire clamps. A partition at the back, which can be pulled out after the removal of the false bottom, gives access to a small shelf-rack containing soldering utensils, and includes a soldering lamp, spirit bottle, jar for acid, and sal-ammoniac and boxes for binding material. The box, with all contents complete, weighs about 120lb., and is arranged for fitters working independently. They are also made for use by assistant fitters.

ALMANACKS, &c.—We have received from the Commercial Cable Company a neatly printed date remembrancer for 1892.

MESSRS. LIRONI, BOWMAN AND CO.—We are asked to state that Mr. V. G. Lironi (late of Messrs. Woodhouse and Rawson and the Elieson Electric Company) and Mr. J. J. Bowman (of Newport, Mon.) have taken over the business until lately carried on by Messrs. Hollington Bros., at the Bow Electric Works, Arnold-road, Bow, E.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

December 21, 1691.

22,316. J. D. F. ANDREWS. London. Improvements in electrical distribution and transformers therefor.

22,326. H. L. CALLENDER. London. Improvements in Wheatstone bridge apparatus, and in the adaption of the same to the measurement of temperatures, electric, potential, and current.

22,339. N. WLADIMIROFF. London. Improvements in primary and secondary batteries.

December 22, 1891.

22,354. G. E. PAINTER. London. Improvements in electric switches.

22,360. J. JACKSON. London. An arrangement for securing good contact in electric switches, and for avoiding dead stops in their action.

22,375. A. BIDRON and W. I. G. LEWIS. London. Improvements in shades for gas, electric, and other lights, and in the mode of manufacturing the same.

22,376. C. S. SNELL and WOODHOUSE AND RAWSON UNITED (LIMITED). London. Improvements in switches for electrical purposes.

22,404. H. W. BOWDEN, A. GAY, and R. HAMMOND. London. Improvements in the coupling of electric mains.

December 23, 1891.

22,473. C. DREVS. London. Improvements in electrical heating apparatus.

22,478. I. A. TIMMIS. London. Improvements in the construction and working of electric accumulators.

22,482. H. H. LAKE. London. Improvements in voltaic cells. (C. Weston, United States.)

December 24, 1891.

22,5?7. R. A. FRASER and G. F. R. KELSON. Liverpool. Improvements in supports for telephone receiving instruments.

22,533. T. JENNER. London. Combined portable electric lamp and battery, which may also be applied to act as a burglar alarm.

22,554. H. H. LEIGH London. Improvements in batteries and accumulators. (J. F. Weyde and F. Class, Austria, and J. Elsner, France.)

22,555. A. BERNSTEIN. London. Improvements in dynamo-electric machines.

December 28, 1891.

22,575. R. KENNEDY. Glasgow. Improvements in dynamo-electric machines.

22,576. R. KENNEDY. Glasgow. Improvements in alternating-current generators and electro-motors.

22,593. F. H. BROWN and W. F. MELBOURNE. Haverfordwest. A combined telephone and telegraph.

22,605. C. F. PARKINSON. Lancaster. Improvements in conduits for electrical conductors particularly suitable for electrical traction.

22,609. R. BALLARD. London. Improvements in incandescent electric lamps.

COMPANIES' MEETINGS & REPORTS.

The Eastern Telegraph Company (Limited).

The thirty-ninth half-yearly ordinary general meeting was held on Thursday, January 14, 1892, at Winchester House, 50, Old Broad-street, London, E.C.; Sir John Pender, K.C.M.G., in the chair.

The SECRETARY (Mr. George Draper) having read the notice convening the meeting, and the minutes of the last meeting, which were confirmed,

The CHAIRMAN said: Gentlemen, I presume that you will take the report as read. You have had it in your hands for some days. Before going into the business to-day, however, I think you will all agree with me that we shall feel the deepest and warmest sympathy with the Royal Family in connection with the dark shadow which has fallen upon them. Probably on no other occasion has news passed so rapidly over this vast Empire as the news of the death of the Prince who has just passed away. The Company in which we are so much interested has been the medium of conveying the sad information to every civilised portion of the world, and thus, I may say, it has been known by them almost within the same space of time as we knew it here. I am sure that the sympathy throughout the world will be as universal and deep as is the sympathy which exists in the more immediate surroundings of the Queen and the Royal Family. We tender to them all our deepest and warmest sympathy. I will now refer to the accounts, and I shall then give every gentleman the opportunity of putting any questions he may desire to put before I submit the resolution to the meeting. Our message receipts for the half-year under review amounted to £321,135, as against, in the corresponding period of last year, £318,728, an increase of £2,407. Dividends from our investments in other com-

Digitized by Google

panies were £33,399, as against £33,455, a decrease of £56. Interest and transfer fees show a falling off of £285. Our gross revenue was £354,939, as against £352.873, an increase of £2,066. The shareholders will remember that on July 1st a considerable reduction of rates came into operation on inter-European telegrams. This reduction, I am glad to say, has been nearly recouped, showing that there is considerable vitality in our business; and wherever there are Europeans using the telegraph that vitality is more marked. Included in the present accounts is the loss on five months' traffic occasioned by the reduction of tariff with Australia. That great reduction to Australia is still going forward, and we have only had about eight months' experience of it. At the end of twelve months, when I next meet you, I think I shall be able to make a very satisfactory report to you. We have already made good smaller losses by increased traffics in other directions; and on the whole we are very well satisfied with the result of the conference that was held twelve months ago. We can only deal with the actual condition of things up to the date when our accounts are made up; but with regard to Australia we are hopeful that a considerable portion of the loss shown at the end of September will be made up by increased receipts before the end of the current financial year. I do not think it desirable to give any figures at this moment, but it must be satisfactory to the shareholders to know that, in spite of the important reductions in the tariff between European countries and with Australia, increased traffic with other countries, where we have not been obliged to reduce our tariffs—notably with South America—enabled us not only to cover the loss resulting from the reductions, but to show a small increase of revenue. The total expenses for the half-year ended September 30, 1891, amounted to £97,130, as against £91,723, or an increase of £5,407. Included in this half-year's figures, however, is the item, for special repairs for buildings at Alexandria and Port Said, £2,450; and the amount carried to the maintenance ships' reserve fund is £4,000, against only £2.500 in the corresponding period. Several of the other items show an increase, while others exhibit a decrease. The details are as follow:—General expenses in London, £9,412, against £8,502, or an increase of £910, the principal being rent, office expenses, and repairs and renewals of furniture, necessitated by the additional accommodation required to meet the demands of the service. Working expenses at stations amounted to £73,097, against £68,435, an increase of £4,662. The additional expenditure under the heading of salaries and wages, rent, fuel, and light, &c., was incurred last half-year, and was fully explained at our meeting six months ago, the necessary increase in the number and additional pay and allowance granted to some of our foreign staff being the cause. The use of patents amounted to £755, against £1,416, a decrease of £661. This is a permanent reduction, some of the patents for which we have been paying royalties for some years having expired. The expenses attending repairs and renewals of cables amounted to £47,048, against £31,478, or an increase of £15,570. In the corresponding period of 1890 the amount chargeable for repairs to cables was exceptionally light, owing to the large credits derived from other companies for the hire our ships for cable repairing purposes. It will be seen from Abstract C, that we have laid in 129 knots of new cable, the cost of which is included in this half-year's figures. The result of this half-year's working is that, although we have a small increase in the gross revenue, we carry forward £57,509, against £78,195 in the corresponding period of 1890, or a decrease of £20,686; but it must be remembered that the half-year to September, 1890, was, as regards ships' expenditure, an exceptionally favourable one. I would call your attention to the important fact that in spite of the large addition which we have made to our cable system during the last six years, the capital expenditure under this head has remained, since 1885, at practically the same figure, notwithstanding that we have laid over 7,000 miles of new cable during that period. This half-year we have applied from the reserve fund the sum of £105,110 in reduction of capital expenditure, and the total amount charged against reserve and revenue accounts to September 30th last is £1,101,463, the balance remaining in our general and other reserve funds being £508,509. I think, gentlemen, you will consider this a very satisfactory position to be in. About eleven years ago the shareholders were good enough to sanction what we called then an insurance fund. A few months ago, when I was addressing the Eastern Extension Company, I drew the attention of the shareholders to an amended system which we are desirous of introducing, and which at the presnt time is in the hands of the actuaries. Telegraphing is a very peculiar business. Probably the youths are, so far as their fingers are concerned, more expert operators than when they become older men. I do not mean to say that their heads are as good, but their fingers are better when they are young; and if we are to get good people around us, we must hold out some benefit to them as an inducement which they will be able to enjoy at the end of a long and arduous life. We think that by encouraging thrift, economy, and generous action on their own part, we should meet that so far by adding to the sum contributed by them, so as to enable each man, after attaining the age of 50 or 60, as we may determine, to retire from the service with a competency. We must bear in mind that our business is not an ordinary business. It is a business in which great confidence has to be placed in the men who work it, and we must have about us a class rather above the ordinary—or rather, I should say, confidential men, well-educated, well connected men—men who would have some little feeling of respect for their names and position; and to secure these men, we require to hold out to them a future rather better than we have been able to hold out to them in the past (applause). We have also to bear in mind that a great deal of our work is conducted in distant countries, in tropical climates, and never in very pleasant places, because we have always to have the bulk of our staff near to where our cable is landed. The consequence is that they live a quiet and lonely life, and not a life which, I think, tends very much to health or to life itself; but still, we always get men ready and willing to go out, though we think it is very advisable that we should be just and generous with the young fellows who enter our service, and to let them feel that we are in touch with them in the course of their working life (cheers). I am glad to hear you signify your approval of that course. I am not going into the details of this scheme to-day. We are working it out most carefully. We have it now before the actuaries, and the whole thing is worked out in such a way that when I put it before you I have no doubt that you will agree that it is fair and just both on the part of the shareholders who constitute the Company and also on the part of the clerks themselves. I am not going to trouble you long to-day. I was looking over the speech which I made six months ago to you, and I think were I to repeat that to-day it would be out of place. I am not going further into details than to say this—that your business is thriving. It is also realising what I have always told you, that every day we live telegraphing becomes a greater necessity. The world could not now move without the system of telegraphy as it at present exists; and as the world grows, so must telegraphy. We are at the head of it, too; our arrangements and appliances are such that we are at the head of everything connected with telegraphy. We have some cables still to duplicate. We have some money yet to spend, but we take care before we spend the money to see where it will come from. We are most desirous, above all things, not to overburden our capital, if we are to keep up a good, steady dividend, such as we are now paying; and when you take into consideration the reduced value of money, and you see that we still maintain our high rate of dividend, I think you may be satisfied that the investment you have made is a good and sound one; and it is believed to be a sound investment by the whole commercial community of this and other places. In spite of the convulsions which have shaken the proudest houses to their foundations, and in spite of the great depression that has been prevailing in commerce, you see the shares of the Eastern and of the Eastern Extension Companies standing rather higher to day than they have done at any former period of their existence. I think I cannot offer you a better evidence of the belief that is held in our property. More than that, you find that our Four per Cent. Debentures are at 108 to 109, which is a further evidence that your property ranks in the forefront among first-class investments. I think I have said sufficient to show you that we are going on pleasantly and satisfactorily. We are going on beneficially for you, and we are satisfying the public that we are anxious to conduct our working in such a manner as to meet with their approval. I hope that as shareholders of this Company you will feel as pleased with the result attained as your Directors do in having contributed towards it (cheers). With these remarks I beg to move—

"That the report and accounts of the Directors to September 30, 1891, submitted to this meeting, be and the same are hereby received and adopted."

The VICE-CHAIRMAN (The Most Hon. the Marquis of Tweeddale): I beg to second the resolution.

The CHAIRMAN: If any gentleman has any question to ask me I shall be very pleased to answer him; but if not I shall put the resolution.

Mr. JOHN NEWTON: I do not think that the important statement which you have made to the meeting should be allowed to pass without some remarks from this side of the table (hear, hear). I think that I am one of the oldest shareholders in the Company, and on former occasions I have criticised very freely the position of the Company. I am, however, satisfied at seeing the prosperity which we now enjoy. Our shares were once only half their present price, and I am sure that those who then held them and who have held them since must be immensely gratified at seeing that the Directors are now going to recognise the services of those to whom we are so much indebted for the improvement in our position, greatly as we are indebted to our Directors. The scheme which you have announced is one which, from what you have said, will greatly benefit the new members of the staff; but I hope you will not forget the older members, who cannot now begin to make any higher payments to this fund (applause). Let those who have served us in the past, in our period of adversity, when I do not think that the remuneration was as much as it should have been, have the full benefit now of what you propose. I have a great deal of pleasure in supporting what you have said.

Mr. WEIR: The last speaker has urged that the claims of the older servants of the Company should not be overlooked; but I feel quite sure that they are in good hands while they are in the hands of our Chairman and his colleagues. I must confess to having had some misgivings when the reduction in the tariff to Australia was submitted to, but I am gratified to find, from what you have said, that matters in this respect are progressing satisfactorily. I should like to make an observation as to the wisdom and the capacity of our Board. Our Chairman has said that during the last three years, while great commercial and financial houses have been shaken to their foundations, the securities of this Company have resulted in a profit of some £16,000, and that in the past half-year. That shows that the securities which we hold are of the highest order. I feel that the Chairman and his colleagues deserve our best thanks for having shown so much prudence and care in the investments which they have made on behalf of the Company.

Dr. WALLER: May I be allowed to say a word? It is most satisfactory to me to find such unanimous and cordial approbation of what the Board is about to do. The gentleman who first addressed the meeting says he is an old shareholder. I am sure that I am an older man than he is, and I believe that I am quite as old a shareholder; but I am what he is not, and what I am glad to see he is—that is, a convert. I am glad to see that a gentleman who was not always cordially disposed towards you is so to-day. That is most satisfactory, and I hope that as this change has taken place it will continue until he is one of the most ardent supporters of this, one of the greatest companies in the world. You have so eloquently indicated all the benefits that will result from the philanthropic scheme to which you have referred, that nothing remains to us at this meeting to say on the matter; but I may say that I am glad to find that a Company like this can be philanthropic. You never, perhaps, did a wiser thing than when you tried to encourage a class of men to our service who will be

Digitized by Google

what you say yourself—faithful and confidential. I believe that a better thing could not have been done (applause). Everything that you say is well said, and nothing could have been better said than what you have said on this subject, and it leaves the shareholders little, or comparatively little to say.

Mr. BAIN: May I ask if all our cables are in perfect working order? On several occasions we have had interruptions at certain places. There is no allusion in the report to this subject, and may I ask you, therefore, if you will refer to it?

Mr. WHISH: Am I right in assuming that we do the whole of our maintenance and repairing work ourselves, and, if so, whether the conclusion has been arrived at that we can do so more economically than by entrusting the work to companies who make such work their special object?

The CHAIRMAN: In reply to the questions which have been put to me I may state, first of all, that we are not forgetting our old *employés*. We have a good many old and faithful servants about us, and we are carrying them, more or less, along with us in what we are doing. I may say we are taking the deepest interest in our young men, but there may be two or three special cases in regard to our old *employés*. I can assure you that we shall never desert our old and faithful servants. There was another question put to me, Whether all our cables are in working order? To that I would say that they are above the average. We are rarely, however, without a broken cable, but having adopted the system of duplicate cables wherever we have the power to do so, the public know little about these breaks now. We had a very important break the other day in the South African cable, which, though not the Company's, is practically owned by this Company; and had we not had our ships in order to attend to this break at once, I think it would probably have been some time before the repair was effected. It is one of the most remarkable instances of the promptitude with which our work is done that that cable was broken and repaired within five days. Had it been in others' hands, or not within our control, it would probably have taken two months to repair. Another question that was asked me was whether we repair our own cables? Yes, we do, and some of other people's also. We never allow our ships to lie idle if we can help it, and we never lose an opportunity of making them earn a nimble penny, because we have always a place where to put it. During the present half-year we earned outside our own Company, by our ships, £15,000, and in the corresponding half-year of 1890, we earned in a similar way, £22,000. You will therefore see that while we are cable workers we are also cable repairers, and not strictly for ourselves, but whenever we can earn a penny from anybody we do so. We think we do this work cheaper than we could have it done for us by others. These are all the questions, I think, that I have to answer, and I dare say you feel satisfied at what I have said. I will now put the resolution. Those in favour of it will please hold up their hands. To the contrary. Carried unanimously. The next resolution is—

"*That Sir A. J. Leppoc Cappel, K.C.I.E., who now retires, be and he is hereby re-elected a Director of the Company.*"

The MANAGING DIRECTOR: I have much pleasure in seconding that.

The CHAIRMAN put the motion to the meeting in the usual way, and, having declared it carried, said: The next resolution is—

"*That Lord Sackville A. Cecil, who now retires, be and he is hereby re-elected a Director of the Company.*"

Mr. JOHN DENISON PENDER: I have the pleasure of seconding that.

The resolution was carried unanimously.

The CHAIRMAN: I think that one of the shareholders has the next resolution to propose.

Mr. WEIR: The resolution relates to the appointment of auditors, and I beg to move—

"*That Mr. Henry Dever and Messrs. Welton, Jones, and Co., both of whom now retire, be and they are hereby re-elected auditors of the Company for the current year at a remuneration of £100 each.*"

Mr. W. GRIFFITH: I am sure that we are indebted to these gentlemen for the work which they do for the Company, and I second their re-election. I regard their remuneration as small, considering the work done by them.

The CHAIRMAN put the resolution, and having declared it carried, said: That, I think, closes the business of this very pleasant and very satisfactory meeting.

Mr. NEWTON: I rise as a convert to propose a vote of thanks to the Directors for the successful way in which they have managed the affairs of our Company, and I think that our acknowledgments are particularly due to our Chairman. I feel, with regard to what has been said, that if certain other Companies had had the straightforward criticisms which in the earlier years of this Company I passed upon it there would not have been so many disasters as we have seen in the commercial world. The Directors of Companies in too many cases have had adulations offered them, whereas criticisms would have been far better in the interests of their shareholders. When we see such results as are now presented to us in the case of this Company criticism is disarmed. Probably there is no joint-stock company in existence which publishes such full and ample details of its position. I sometimes think now that I urged too much when I spoke in favour of your publishing fuller details, because I sometimes think that you lay your business too bare. Fortunately, however, we have not too many competitors, having one of those beneficial monopolies which advantages everyone. I think I shall be in order now by proposing this resolution, giving our thanks to the Chairman and the Directors.

Dr. WALLER: I claim the right to second this resolution, so that I may make an observation to my good friend the convert. I know nothing more creditable to a man's candour and judgment than when he finds he has been in the wrong he unhesitatingly turns and acts in the right. I hope that he will long continue to give his able assistance now in your favour.

Mr. NEWTON put the resolution to the meeting, and it was carried unanimously.

The CHAIRMAN: Gentlemen, on behalf of my colleagues and myself I very warmly thank you. There is no encouragement so great, so stimulating, as that of the approval, six months after six months, of the body of our shareholders in the work that we have done. Dr. Waller has been a kind and generous supporter for a great many years; for we are getting old now in our work. I may say for Mr. Newton that he was once a very hard master; but, after all, when I look back, I see that he had a good deal of justice on his side. I may tell Dr. Waller that it was a long, a tough, and a very hard job to convert Mr. Newton, and we did not convert him entirely until he saw that the whole thing was conducted properly, and that we were all doing what we ought to be doing. When I look round at these meetings, and remember the days that are past and gone, the opposition we had, and the determined way we persevered, I should feel regret, and deep regret, if I missed Dr. Waller and Mr. Newton from our gatherings. The men who have known us from the beginning and who have stood by us to the end are the men I admire. Whenever they can point out anything in our conduct that ought to be amended, you may depend upon it that very full consideration will be given to the matter. I may say that I am going away for a couple of months to get beyond the cold weather that is prevailing here; but I may state that I am going to some of our stations in the Levant and other places, and therefore I shall again come in contact with our work-people. You would be astonished to see how delighted they are at receiving a visit from the Chairman. The more we can keep in touch with our *employés* the better we shall get our business done, and greater efficiency will be the result.

The proceedings then terminated.

Direct United States Cable Company (Limited).

The twenty-ninth ordinary general meeting of this Company was held at Winchester House, 50, Old Broad-street, London, on Friday, 15th inst., under the presidency of Sir John Pender, K.C.M.G.

The SECRETARY (Mr. T. Finnis) read the notice convening the meeting and the minutes of the last general meeting.

The CHAIRMAN then said: Gentlemen, this meeting being duly constituted, I think you will all agree with me that we ought to give expression to our deep and warm sympathy with the Royal Family in the great bereavement which they have sustained by the death of the Duke of Clarence. I believe that this sympathy is universal. Only a month ago the country was jubilant at the prospect of a marriage which would give increased strength to the Crown. That prospect has passed away, and I may say that that doubly increases the sorrow which we all feel at this sad event. Passing to the business of the meeting, he said: I shall, as usual, go over some of the figures of the report, in order that you may have more complete knowledge of the working of our system during the last six months. The revenue for the half-year to December 31st last, after deducting outpayments, amounted to £45,402, and the working and other expenses, including income-tax, but exclusive of the cost of repairs, absorbed £17,673, leaving a balance of £27,729 as the net profit of the half-year, making, with £3,502 brought forward from the previous half-year, a total of £31,231, which has been appropriated as follows:—Interim dividend of 3s. 6d. per share for the quarter to September 30th, £10,624; interim dividend of 3s. 6d. per share for the quarter to December 31st, £10,624: amount set aside for reserve fund, £5,000; balance carried forward, £4,933, making a total of £31,231. The revenue, as compared with that of the corresponding period of the previous year, shows an increase of £2,055, but the traffic generally has not been brisk. The McKinley tariff has, no doubt, restricted trade in many quarters, and but for the large operations in grain owing to the deficient harvest in Europe, our revenue would probably have shown a falling off. The expenses in London show as follows: Increases of £129 in salaries, and £13 in office expenses, and a reduction of £23 in printing and stationery, the remaining items being practically the same as heretofore. The expenses at stations show increases of £375 in salaries, wages, and allowances, and £63 in rent, rates, and taxes; and reductions of £40 in maintenance, £21 in travelling, £78 in repairs and renewals, and £37 in printing and stationery. These expenses on the whole show an increase of £290, largely due to the new branch station at Spruce-street, New York, referred to in my remarks at the last half-yearly meeting. In the remaining expenditure a reduction of £159 is shown in insurance and storage of cable, while on the other hand a sum of £730 is written off for depreciation of spare cable and cable tank. The reserve fund account has been charged with £4,478 for cost of repairs of cable. At the same time it has been credited with £4,303 interest on the investments, and with £5,000 from the revenue account, increasing the balance of reserve fund to £259,680. 8s. 8d. The investments remain unaltered from last half-year, and their present market value continues considerably in excess of their cost to the Company. Now, gentlemen, these are the hard facts connected with last half year, and in looking over the remarks which I made when I addressed you six months ago I find that I told you then everything that I could possibly bring before your notice which would interest you. To-day I have very little further to say than that we are going on fairly well. The McKinley tariff, as I have said already, rather interferes with us, but that has been pulled up to some extent by the increased traffic caused by the conveyance of grain, and also by the general movement in America at the present time in regard to railway stocks. As I have said before, whenever there is a movement in that way we get some share in it, as shown by

Digitized by Google

our returns. There is no doubt also that the preparations for next year's Exhibition will help us to some extent; but still, we have got this fact to face—that we have rather more cables in the Atlantic than are required to do the work, and until such a growth of traffic comes as to fully employ these cables, I do not think we can look forward to any very large increase in our returns. I see in the papers—and I daresay you also see it as well, and ask yourselves why it should be so—that the Commercial Cable Company's shares are selling somewhere about £150. I believe there is very little of that stock held in England, but I believe a good deal of it is held in Canada, where a large amount of it was bought some years ago; but it is held in only a few hands, and they might just as well make it 200 as 150, as far as the general public is concerned. Is there any reason why that stock should be at that price when Anglo-American stock and our stock is at about 50 per cent. discount? With the price quoted of £150, the Commercial Company pay 7 per cent. upon their nominal capital, but taking it at that advanced price it only gives the man who buys it £4. 13s. 4d. per cent.; whereas any man can buy our shares at 50 per cent. discount, or very nearly so. We are paying 3½ per cent. upon our par value of £20; so the man who buys our shares gets 6¾ per cent. or 7 per cent. for his investment, against about 4½ per cent. on his investment in the Commercial Company. That is a very striking figure, and any man who has watched this thing will probably satisfy himself that, after all, there must be some reason other than the working of the cable to account for the market price. The Direct Cable probably carries messages in the shortest space of time that they have ever been conveyed across the Atlantic. We carried the news of the Derby one year in less than a minute to New York. The Anglo Company has four cables, the Western Union two cables, and we have one cable, so that we are working with seven cables against the Commercial Company's two cables. We know that the command of the carrying power, as we have it, enables us to convey the traffic quicker than it can be done by any other means; and therefore I hold that there is no reason that I can see for the price which I have mentioned being quoted for the Commercial Cable Company's stock, except for a certain amount of prejudice and a certain amount of sentiment. Whether its price will be maintained it is impossible to say; but if you take my advice, I say rather invest and get 7 per cent. out of something that may rise to par, than invest in something that may go down to par. This is almost all that I have to say to you. During the past six months we have had one repair, and I am glad to say that in the course of effecting that repair we took up a part of the cable, which satisfies us that, although our cable has attained the good age of 17 years, it has a considerable number of years of "life" in it yet. Every repair we make we put in new cable, and I think I may say that our belief in the "life" of cables is growing. Whenever a cable is broken we never lose time in making the repair, a ship being sent out promptly to do the work. That is not generally the case with cable repairs, but we think it right to remedy as soon as possible any interruption that may take place. I hope when I see you next time that I shall be able to tell you that we are going on satisfactorily. So far, I do not think anyone has any reason to complain. You can buy our shares to-day to give you 6½ per cent. or 7 per cent., and I do not think that that is a bad return. With these remarks I beg to move:—

"*That the Report of the Directors, dated January 5, 1892, together with the statement of accounts to December 31, 1891, annexed thereto, be and the same are hereby received and adopted.*"

Mr. WILLIAM FORD: I beg to second the resolution.

The CHAIRMAN then invited discussion; but no one rising to address the meeting, he put the resolution, which was carried.

A vote of thanks to the Chairman and Directors was then proposed, seconded, and carried unanimously.

The CHAIRMAN, in reply, said: I am very much obliged to you for your kind words. We are doing our very best to promote the welfare of the Company. It is a pleasure to meet you every half-year, but it would be still more pleasant to me if I could tell you that we were going to give you an extra ½ or 1 per cent. However, I hope good times are coming, and should they arrive you may depend upon it that we shall be able to take advantage of them, and in that way you will be benefited.

The proceedings then terminated.

Anglo-American Telegraph Company (Limited).

The following is the report of the Directors, to be presented to the ordinary general half-yearly meeting of the proprietors, to be held at Winchester House, 50, Old Broad street, London, E.C., on Friday next, the 29th inst., at 2 p.m.

The total receipts from July 1st to December 31, 1891, including the balance of £527. 4s. 10d. brought forward from the last account, amounted to £164,121. 9s. 4d. This sum, however, is subject to revision, as the lawsuit between this Company and the Paris and New York Telegraph Company is still pending before the Court of Appeal. The traffic receipts show an increase of £6,157 as compared wfth the corresponding period of last year; but, as will be seen from the revenue account, this sum includes the adjustment of balances to June 30th last. The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amount to £63.507. 3s. 4d.

Interim dividends of 12s. 6d. per cent. on the ordinary stock, and £1. 5s. per cent. on the preferred stock, were paid on the 31st October last, absorbing £43.750, leaving a balance of £56.864. 6s., out of which the Directors recommend the proprietors to declare final dividends of 16s. per cent. on the ordinary stock, and £1. 12s. 6d. per cent. on the preferred stock, amounting to £56,000, making a total distribution for the year ended December 31, 1891, of £2. 12s. 6d. per cent. on the ordinary stock, and £5. 5s. per cent. on the preferred stock, leaving £864. 6s. to be carried forward to the next account.

The Company's repairing s.s. "Minia" has been engaged during the past half-year in the repair of the 1880 cable, the Brest St.-Pierre cable, the North and South Placentia cables, and the Duxbury cable. The "Minia" has also been employed in laying a cable from North Sydney, Cape Breton, to Canso, Nova Scotia, connecting this Company's system with the Western Union Company's cables between Canso and New York, thus providing an additional and alternative route, which, in the event of sudden pressure of business, or breakdown on the land lines, will be of great value. The new line completes through cable communication between England and New York City. The cost of the new cable has been charged to renewal fund.

The Company's cables and land lines are in good working order, with the exception of the Brest-St.-Pierre cable, which was again broken on November 18th last, at about 275 miles from Brest.

It is expected that the law-suit still pending between the Anglo Company and the Paris and New York Telegraph Company will be argued before the Appeal Court of Paris during the course of the coming month.

In accordance with the Articles of Association, two Directors of the Company, Francis A. Bevan, Esq., and Charles Burt, Esq., retire at this meeting, and being eligible, offer themselves for re-election. Mr. Joshua Dean and Mr. John Gane, F.C.A., the auditors, retire, and offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

CENTRAL ENGINEERING AND SHIP REPAIRING COMPANY (LIMITED).—This Company was registered on January 12, 1892, with a capital of £9,000, in £10 shares, by Kerr and Lanham, 3, Chichester-rents, Chancery-lane, London, W.C. The objects are to acquire and carry on the business of shipbuilder, ship repairer, engineer, engineering tool maker, tin and copper smith, boiler maker, iron and brass founder, &c., carried on by Mr. D. J. Morgan and others at the Central Engineering and Ship Repairing Works, Bute Docks, Cardiff.

TYNE DOCK LAND COMPANY (LIMITED).—This Company was registered on January 12, 1892, with a capital of £60,000, in £12 shares, by T. W. Rossiter, 7, Ely-place, London, E.C. The objects are to enter into an agreement with the Jarrow Chemical Company (Limited) and John Stableford, its liquidator, being a reconstruction agreement of the said Jarrow Chemical Company (Limited), and to sell for cash or for fully paid up shares in any other company the Company's shares and interest in two patents granted to James Shannan Stevenson for "Improvements in the manufacture of elements or plates for secondary batteries or electrical accumulators" and "Improvements in or connected with the manufacture of secondary battery elements," acquired under the reconstruction agreement.

AMERICAN CAMERA COMPANY (LIMITED).—This Company was registered on January 13, 1892, with a capital of £15,000, in £1 shares, by J. Boss, 10, Colchester-street, London, S.W. The objects are to acquire and take over as a going concern the business carried on by Mr. Walter P. O'Reilly, under the style of the American Camera Company, at 397 and 399, Edgware-road, W., and 124, Old Broad-street, E.C., of manufacturers and dealers in photographic, electrical, optical, chemical, and scientific instruments, apparatus, and requisites of every description.

ELECTRICAL ADVERTISING SYNDICATE (LIMITED).—The statutory return of the above Company named, made up to December 29, 1891, was filed on January 12, 1892. The Company was registered on April 27, 1891, with a nominal capital of £10.000 in £10 shares, to acquire all or any patents or such parts or shares thereof as may be agreed upon, for Upward's method and apparatus for the application of electrical energy to the purposes of advertising, and to work the same. At the time of making-up 907 shares have been taken up, and, although nothing has been called on any of the shares, £9,070 has been paid. Registered office: Victoria-mansions, Victoria-street, London, S.W.

ELECTRIC WELDING COMPANY (LIMITED).—The first annual return of the above-named Company, made up to January 5, 1892, was filed on the 14th following. The Company was registered on May 1, 1890, with a capital of £460,000, in £10 shares, to acquire and work certain patents in connection with the welding, forging and brazing of metals by electricity. The shares are now divided into 45,000 ordinary and 1,000 founders' shares. At the time of making up, 25,000 ordinary and 617 founders' shares had been taken up, and upon 16,667 ordinary shares £6 per share had been called, while upon the founders' shares the full amount had been called. The remaining 8,333 ordinary shares had been issued and considered as fully paid. The calls paid amount to £70,726. 10s., while the calls in arrears amount to no less than £102,113. 10s. A glance through the list of shareholders shows that many are resident in America, most of them hold 49 ordinary and 1 founders' share. Registered office: 6, Great George-street, Westminster, London, S.W.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The Directors have declared an interim dividend upon both the ordinary and preference shares of the Company at the rate of 6 per cent. per annum for the six months ended December 31st last, payable on February 15th next. The transfer books of the Company will be closed from the 20th to the 27th instant.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended January 17th amounted to £836, as against £765 for the corresponding period of 1891, an increase of £71.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—A circular has been issued by this Company in which the Directors offer the

Digitized by Google

unissued ordinary shares (9,848 in number) to the shareholders on the Company's register on January 14th inst., as was arranged at the recent statutory meeting. The shares are issued *pro ratâ*. The first payment of £3. 5s. per share is due to-morrow (Saturday), and unless this amount is paid on or before that date the allotment is forfeited. After the second payment of £3 per share on February 1st next the shares now to be allotted will rank *pari passu* in all respects with the existing shares.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY.—This Company announce the payment, by warrant on February 1st next, of the interest for the half-year ended January 31st on their Four per Cent. Mortgage Debenture Stock. The transfer books will be closed from the 27th to 30th instant, both days inclusive.

ELECTRIC FITTINGS HIRING AND MAINTENANCE COMPANY (LIMITED).—The Directors of this Company announce that one founders' share will be placed at the disposal of every subscriber for 50 ordinary shares in the Company.

NATIONAL TELEPHONE COMPANY (LIMITED).—Mr. James Staats Forbes, one of the vice-presidents, has been unanimously elected the President of this Company, in succession to the late Mr. Frederick Richards Leyland.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the two weeks ending January 15, 1892, were £2,331, as compared with £2,792 for the corresponding period of last year, a decrease of £461.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 715.—Vol. XXVIII. FRIDAY, JANUARY 29, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

Although the second half-year's working of the City and South London Railway has not brought financial consolation to the holders of the Ordinary shares, the Directors are able to go one stage further in the dividend-paying process and pay 5 per cent. on the Perpetual Preference shares in addition to the Debenture interest. The gross receipts show an increase of nearly 8 per cent. over those of the first half of 1891, while the working expenses remain practically stationary. The number of passengers has increased by 14 per cent., the total carried since the opening of the line on December 18, 1890, being close upon 5½ millions.

It is a great pity that so much unnecessary secrecy and unexplained delay has postponed the publication of the Lauffen-Frankfort transmission experiments. If the plant had been erected for some industrial purpose, business reasons might have interfered, but it was set up as a leading feature of a popular exhibition. An exhibition, if aiming at something more than providing a tea or beer garden, is nothing if not demonstrative, and fails in its purpose if it does not set forth in full and disclose completely the objects for which it has been held. Some figures relating to measurements of the multiphase plant have been semi-officially published in the *Schweizerisch Bauzeitung*, and are to be found in another column. The efficiency, exceeding 72 per cent., is very satisfactory, but the information is altogether too vague to enable fair comparisons to be made with other systems. The proportions of capital outlay which were devoted to plant and to the conductor are interesting, but £10 per horse-power for the former, if accurate and inclusive, is, perhaps, a strong point; since it is a fair proof, not so much of economy, as of simplicity of construction, and, therefore, of cheapness of up-keep.

The ingenious suggestions which were put forward by Prof. FitzGerald at the Physical Society last week, and to which Mr. Garrett makes an interesting addition in his letter which appears in another column, deserve careful experimental investigation. The expenditure of energy which would be required to maintain the oscillations would be inconceivably small in the presence of a well-tuned resonating apparatus; and if there is any remote chance of success each method should be given a trial. It has been said, and it is still safe to say, that no well-informed electrician would in 1875 have seriously contemplated for a moment the construction of a pair of Bell telephones as transmitting and receiving instruments even for musical sounds, to say nothing of articulate speech. The marvel that the quiver of an iron diaphragm can set up an appreciable current is equalled only by the greater marvel that these currents can generate an audible sound at a distance of many miles. If a battery contained in a thimble will deflect a magnet loaded with a mirror at the remote end of an Atlantic cable, what a tiny effort, if properly applied, may deflect a spark and determine which of two knobs it shall strike! If a clock hanging on a nail can impart such impulses through a wall as can affect the motion of the pendulum of another clock, such minute differences of potential as may be set up in a bismuth wire might maintain the oscillations of a current in the manner suggested by Mr. Garrett.

Mr. Garrett's device is remarkable in one respect, inasmuch as it is possible by its means to produce a current alternating at the same frequency as the original current, or twice as rapidly. The alteration in the resistance of the bismuth depends only on the strength of the magnetic force, and not upon its direction, so that the alternating magnetic field due to the current in the solenoid will cause the secondary current to fluctuate twice as often as the primary. If, however, a permanent magnetic field be superposed upon the weak field due to the current in the coil, so that the direction of the lines of force is always the same, the two currents will be of the same frequency. There seems, however, slender hope that this device will be useful for the purpose suggested. Apart from the doubt whether bismuth would respond to the influence of such rapid currents, the strength of the field produced by electric oscillations is so small that the effect on the bismuth would be infinitesimal; and, moreover, the impedance presented by the solenoid to such oscillations would be so enormous that the current would probably find it easier to spark across the terminals than to traverse the coils.

Our correspondent who thinks that we shall scarcely endorse the opinion which we have already cited, to the effect that an attempt to answer the question "What is Electricity?" is to waste time, is mistaken; for we are beginning to think that the present discussion is not only a waste of time but a waste

Digitized by Google

of our space. The two letters which we publish this week are undoubtedly heterodox; and while it is only fair that such views should have a hearing, we shall have to close our columns to any more contributions of this character.

MR. PAULL does not appear to have studied Prof. OLIVER LODGE'S "Modern Views," and seems to have had only second-hand information on Prof. POYNTING'S contributions to our knowledge of energy-paths. A much less important omission on the part of our correspondent is the perusal of a theory which we ventured to put forward in the article which gave rise to this correspondence, and which appeared in our issue of December 18th. We assumed a magnetic molecule, and defined its magnetism as the property whereby a strain is set up in the neighbouring ether. This postulate, we think, is a modest one in the present state of our knowledge of magnetism. We went on to say that, this being granted, it is only necessary to assume that if relative motion is produced between this molecule and a conductor, all electrical phenomena may be accounted for, and no conception of "current" or "electricity" is in the least necessary. None of our correspondents have noticed this theory; and until it is demolished we see no reason whatever for supposing that electricity exists, and, *à fortiori*, that a current ever flows.

THE information which Mr. SYDNEY MORSE is good enough to give us on the subject of Rural Sanitary Districts and Urban Sanitary Districts will be appreciated by those of our readers who may meet with these phrases in their dealings with Corporations and other local bodies. We have no fears that the Board of Trade will take a hint from our remarks and prohibit the use of overhead wires in the "Urban" districts. We have heard these names used in connection with the difficulty of defining "town" and "country," and it is highly probable that the Board of Trade have already satisfied themselves that to accept this "sanitary" definition in connection with overhead wires would press too harshly on electric lighting.

Jarrow.—The Corporation are inviting electric lighting tenders for supplying private customers with the electric light.

Appointment.—M. Violle, of incandescent platinum standard fame, has been appointed M. Edmond Becquerel's successor at the Conservatoire des Arts et Metiers.

Applied Electricity.—Mr. W. Perren Maycock will lecture on "Applied Electricity," on Wednesday next, at 8 o'clock, at the Whitgift Grammar School, Croydon.

Bermondsey.—At a recent meeting of the Bermondsey Vestry the General Purposes Committee reported that they had instructed the surveyor to ascertain upon what terms the streets could be lighted by electricity, as from March 25th next.

The Price of Aluminium.—The Aluminium-Industrie-Actiengesellschaft, of Neuhausen, says *Industries*, has recently reduced its price for pure aluminium from £40 to £25 per 100 kilogrammes. The daily production at these works now amounts to one ton.

St. Petersburg Electrical Exhibition.—The St. Petersburg Electrical Exhibition was formally opened on Saturday last by M. Vishnegradski, Minister of Finance, who was accompanied on the occasion by M. Durnovo, Minister of the Interior, and a number of distinguished personages.

Royal Society.—The following papers were down for reading yesterday before the Royal Society: "On the Melting Points of the Gold-aluminium Series of Alloys," by Prof. Roberts-Austen, F.R.S.; and "Colour Photometry," by Captain Abney, F.R.S., and Major-General Festing, F.R.S.

Electric Traction in Russia.—The first electric street railway in Russia, says the *Engineer*, will be constructed in Kiew, a city of about 130,000 inhabitants, and situated on the river Dnieper. This street railway will use the overhead system, and will be ready for operation in the summer.

Clothworkers' Scholarship.—This scholarship, entitling the prizeman to five years' training at the Finsbury Technical College and the Central Institution, together with a sustentation allowance, has again been won by a pupil of the St. Thomas Charterhouse Schools, E. Dixon, aged 13½ years.

The Electric Supply Mains at Liverpool.—There was a small scale repetition on Wednesday morning last week of the short-circuit fire which took place a few days previously in one of the supply boxes of the Liverpool Electric Supply Company (see *The Electrician*, January 15th, p. 269).

The Leeds Electric Tramway.—Since the opening of the Roundhay Park line Mr. Graff Baker's cars have carried 90,000 passengers, the aggregate daily mileage being 500 miles. The maximum numbers of passengers which can be carried in any single day is 6,000, a limit which was reached on Boxing day.

The Howard Lectures.—In consequence of the illness of Prof. W. C. Unwin, F.R.S., the Howard Lectures on "The Development and Transmission of Power from Central Stations," which he was announced to deliver before the Society of Arts on February 5th and five following Friday evenings, have been postponed.

Coast Communication.—A Government Commissioner has just been visiting several ports on the Bristol Channel coast with a view of obtaining information and suggestions to lay before the forthcoming Commission, which will investigate the whole matter of improved communication by telegraph along the sea coast.

The Probable Future of Condensers in Electric Lighting.—In Mr. Swinburne's article on this subject, which was reprinted from *Industries* in our issue of January 1st, there was an error as to the exciting current of the triple-current motor mentioned on p. 228. The exciting current of a two-horse motor should be 3 amperes in each circuit, making 630 apparent watts at no load.

Mr. Edison.—We learn from our Correspondent in Russia that Mr. Edison is expected to arrive at St. Petersburg next week, with the object of inspecting the Electrical Exhibition and being present at some of the experiments which are being made there with the machinery exhibits. The Americans in St. Petersburg are making great preparations to give Mr. Edison a cordial reception.

Dublin.—The installation of the electric light by the Dublin Corporation is going on so far favourably. The engine and dynamo building is all but complete, and the laying of the mains in the compulsory area is progressing rapidly. The mains are laid underneath the flagway, near the edge of the footpath. Metal junction boxes are being fixed at the angles of branch streets, and for every two houses a service box is inserted, so that service wires for each two houses may be taken from one point in the main.

Electrical Engineering Course at Sydney University.—The University of Sydney have recognised the claims of electrical engineering by adopting the following proposals by Prof. Threlfall at the last meeting of the Senate:—"That the faculty cordially approves of Prof. Threlfall's proposal for the establishment of a curriculum in electrical engineering, and recommends that it be carried out by the Senate, including the suggestion of a grant of £300 for the necessary apparatus." It was also decided that the curriculum should lead up to the degree of Bachelor of Engineering in Electrical Engineering.

Chicago Exhibition.—The first meeting of the Electricity Committee of the Royal Commission was held on Tuesday afternoon, 26th inst. Present:—W. H. Preece, F.R.S., in the chair; Sir Frederick Abel, F.R.S., Colonel R. T. Armstrong, R.E., R. E. B. Crompton, Prof. James Dewar, F.R.S., Major-

Digitized by Google

General E. R. Festing, F.R.S., Prof. George Forbes, F.R.S., Prof. G. Carey Foster, F.R.S., Edward Graves, Prof. D. E. Hughes, F.R.S., Gisbert Kapp, J. C. Lamb, W. M. Mordey, J. Fletcher Moulton, F.R.S., Prof. John Perry, F.R.S., Alexander Siemens, Prof. Silvanus P. Thompson, F.R.S, with Sir Henry T. Wood, Secretary of the Royal Commission.

The Association for the Improvement of Geometrical Teaching.—Messrs. Whittaker and Co. inform us that they have been appointed the London publishers of the general reports of this Association. In addition to the Papers mentioned by Mr. Langley on p. 284 of our issue of January 15th, and to the Papers read at the recent general meeting of the Association (see *The Electrician*, January 15th, p. 273), the following appear in the General Reports:—A Geometrical Investigation of (i.) Frégier's Point (G. T. Bennett, B.A.), (ii.) Cosh $u + \sinh u = \exp(u)$ (R. Levett, M.A.); Geometrical Theorems (Dr. J. S. Mackay); Geometrical Odds and Ends (E. M. Langley, M.A.).

Obituary.—Mr. Alexander Watt, whose death occurred on Friday, January 15th, was born in 1823. In 1839 he took up the then novel process of electrotyping. In 1885 he published a treatise on "Electro-Deposition." In the year 1887-8 he contributed a series of Papers to *The Electrician* on "The Electrolysis of Iron Salts," and to the *Electrical Review* Papers on the "Electrolysis of Aluminium Salts," "Electrolytic Coloration of Metals," &c., &c. Mr. Watt gave practical instruction and advice to a considerable number of persons in the art of electro-deposition, both at home and abroad, and had been engaged in several important electrolytic lawsuits. He also delivered occasional lectures on the electro-deposition of metals and other subjects, and was the author of a number of works upon the subject of "Electro-Metallurgy," "Electro-Deposition," &c.

Electric Traction and the Liverpool Tramways.—At the recent meeting of the shareholders of the Liverpool United Tramways and Omnibus Company, the Chairman remarked that they seemed to be still no nearer to a system of mechanical haulage that would supersede horses. Electricity answered well as a haulage power, but commercially the price was far more than horses. They had an offer of electrical haulage at 7d. per mile, with an additional charge of £1,600 for each car, with its electrical machinery attached. The 7d. per mile was much more relatively than the cost of horse haulage, exclusive of the capital outlay of £1,600 for each car; and, as they had 234 cars, the total outlay would amount to £374,400. The same Company offered the Glasgow Corporation the same service at 3½d. per mile, the physical difficulties of Liverpool accounting for the enormous difference.

Electric Light Competition in Holborn.—At a recent meeting of the Holborn Board of Works Mr. Claremont, of the Metropolitan Electric Supply Company, waited on the Board to ask them not to consent to the application of another company to supply Holborn with electric light. There was not sufficient demand in Holborn, he said, to warrant the establishment of another company in the district. His company had left no stone unturned to do justice to Holborn. They had endeavoured in every way possible to give satisfaction, and had never had a complaint or a breakdown; and, besides, their price was cheaper by ¾d. a unit than that of any other company in London. In reply to a member, Mr. Claremont said that the company's station was capable of supplying far more light than they had application for. Mr. Moss, on behalf of the County of London Electric Company, asked the Board to assent to the application of his company. The Board decided to grant the application of the County of London Electric Company.

Interurban Telephony in Bulgaria.—The new telephone service between Sofia and Philippopolis, a distance of a hundred miles, was recently inaugurated with considerable ceremony by Prince Ferdinand. Prince Ferdinand inaugurated the new line with a patriotic speech, addressed to the Prefect of Philippopolis, which was greeted with loud applause, and to which the Prefect made a suitable reply. The Ministers present, and several others who were invited to do so, then spoke by telephone with persons at the Philippopolis end of the wire. The hearing was perfect. At Philippopolis the inauguration was attended by the Prefect, the clergy, the chief civil and military officials, and the consular body. After the exchange of a considerable number of communications, those present at the ceremony, both at Sofia and at Philippopolis, were entertained at *déjeûners*, at which several patriotic addresses were delivered, the speakers dwelling especially upon the progress made by the principality, of which the establishment of telephonic communication between the two chief cities afforded a fresh proof.

Electrical Bills in Parliament.—Among the Bills which have passed the Examiners on Standing Orders of the House of Commons are the following:—The New Telephone Company, Baker-street and Waterloo Railway, Waterloo and City Railway, Great Northern and City Railway, London County Council (Subways), Central London Railway, Liverpool Overhead Railway, the National Telephone Company and the Ward Electrical Car Company Bill, authorising agreements between the Company and local authorities for the running of electrical carriages in the streets. In the case of the London, Tottenham, and Epping Forest Railway Bill, which appeared on the list, no appearance was entered, and it was struck off. The Bill of the New Telephone Company is a measure for dissolving and reincorporating the Company, and defining its capital, objects, and powers. The clause of the Bill which relates to capital recites that the capital of the Company shall be £75,000, divided into 74,700 shares of £10 each and 3,000 founders' shares of £1 each, but the Company may from time to time increase its capital to an amount not exceeding £2,000,000.

Sunderland—A special meeting of the Highways Committee of the Corporation has been held to consider offers for lighting with electricity that part of the town comprised in the Provisional Order (1891). Applications had been invited by the Corporation from companies prepared to take over the powers which the Provisional Order vested in them. Two were received, viz., from the Brush Company and Messrs. Andrews and Co. The former proposed to take over the Order with all its obligations, on condition that the Corporation assisted them to form a local company, that at the end of 21 years the Corporation should have power to acquire the works as a going concern at a valuation and payment to be agreed upon for the goodwill, that they would pay a royalty of 10 per cent. on the balance of receipts over expenditure, that the Corporation should cause the main thoroughfares to be lighted at such a price as should be arranged hereafter, and that no concession of any kind should be granted to any other company. Messrs. Andrews proposed to take over the area mentioned in the Provisional Order, to supply it with electricity for lighting purposes on the alternating-current high-pressure system at a uniform charge of 3¾d. per Board of Trade unit, and to pay the Corporation a rental of £100, together with a royalty according to the consumption. They required payment for the goodwill if at the end of 21 years the Corporation wished to acquire the concern. The terms of both offers were discussed, and it was ultimately agreed to submit the same to Mr. Shoolbred, and to await his report.

Central Station Lighting in Halifax.—The Halifax Mutual Electric Light and Power Company was formed nearly two years ago by taking over the central station then being worked by Messrs. Blakey, Emmott and Co., and also that of an opposition company which has since ceased to exist. The wires, by permission of the Halifax Corporation, are all overhead, and the Company is supplying current for about 60 arc lights of 10 amperes, and 1,000 incandescent lights of 8 c.p. Two systems of charging are adopted in the town, viz., one at the rate of 12s. per 8-c.p. lamp per annum, and £12 per 10 ampere lamp per annum, and at 8d. per B.T.U. The furthest point served from the central station is about 1,700 yards. The low-tension system is adopted throughout. It has been found during the past two months that the Company could not keep pace with the large demand for current at their present premises; therefore, negotiations have been entered into with the Halifax Corporation for leasing from them a convenient site, and very shortly it is hoped that the Company will have a capacity of at least 20,000 8-c.p. lamps. Two systems of engines are used

Digitized by Google

for driving, viz., Armington-Sims High Speed, and Tangyes. The dynamos and all other electrical fittings in connection with the installation are of the Blakey, Emmott, type; and Mr. Walter Emmott, of Blakey, Emmott, and Co., is the managing director. The meter adopted up to the present has been the "Aron," which appears to be giving general satisfaction both to the Company and to the consumers. The price per 1,000 cubic feet of gas in Halifax is 2s. net, and judging from the weekly reports of the expert who tests the illuminating power on behalf of the ratepayers, the average illuminating power is about 17 candles. Taking into account this very low price and high efficiency, the present output and very large demand for current speak very well for the prospects of electric light for the future. The whole of the wires and cables for this installation have been manufactured by the Northern Electric Wire and Cable Manufacturing Company, Halifax.

Central Station Lighting at Preston.—A temporary generating station was fixed twelve months ago, for the purpose of ascertaining the probable demand for the electric light in Preston. The National Electric Supply Company, which Company has obtained a Provisional Order for lighting the town for a term of 42 years, intended the maximum output of this station to be only 1,000 8-c.p. lamps; but long before the plant was ready for working, this number of lamps was quickly taken up on a basis of 12s. per lamp per annum. The Company to meet additional orders was compelled to fix another machine, bringing the capacity up to considerably over 2,000 lights, which quantity is now actually working, and orders for more are daily coming in. The outside wiring up to now has been overhead, there being four circuits from the central station in Corporation-street, two along pole routes through the most important thoroughfares in the town, and two over housetops, telephone fashion. The present plant, supplied by Messrs. Blakey, Emmott and Co., of Halifax, consists of three 18-unit machines and one 30-unit machine. The National Electric Supply Company now propose to put down a plant on the low-tension system similar to that now working so successfully in the St. James' district in London. The first portion of the town to be served from this station will be the compulsory area with the adjoining streets, in which it is anticipated that at least 20,000 8-c.p. lamps will be required. Distributing boxes will be laid to such places so as to ensure an even potential over the mains. A large number of meters has been introduced. The amount charged to consumers is 8d. per Board of Trade unit, with a discount of 15 per cent. if paid within 21 days. Preston with its numerous mills is favourably placed for a successful adoption of the electric light, and the way in which the engineer and manager Mr. F. F. Bennett has worked up the present installation augurs well for the future. Gas at Preston is 2s. 9d. per thousand.

The Recovery of Wasted Gutta-Percha.—In a recent number of the *Kew Bulletin* is reprinted a report of Mr. Leonard Wray, jun., dated Perak, September, 1883, on the subject of the recovery, by appropriate processes, of the vast quantities of gutta-percha wasted by the methods of collection at present in vogue. In view of the sanguine anticipations of M. Eugene Serullas in this direction, the following extracts from Mr. Wray's report may be of interest. After describing the present wasteful method of felling trees, and then cutting V-shaped notches in the bark into which the gutta-percha gradually oozes, Mr. Wray goes on to say that the amount of gutta-percha obtained from a single tree has been greatly over-estimated; exceptionally large yields from gigantic trees having been erroneously quoted as averages. Mr. Wray had a tree felled, 2ft. in diameter at a height of 6ft. from the ground, and about 100ft. high, and 100 years old; *it gave 2lb. 5oz. of fairly-clean gutta, worth only 7s. 6d.* A tree was next felled and treated in the usual Malay manner, 12oz. of gutta being obtained. Samples of the bark were then treated by various processes, simple and elaborate. The following deductions may be made from these results: firstly, the wet bark which is allowed to rot in the jungle contains fully 5·7 per cent. of its weight of gutta, or when dried 11·4 per cent.; secondly, by simply pounding or rasping and boiling the bark, nearly all the gutta which it contains may be extracted. The total weight of wet bark on the tree in question was 530lb. 5·3 per cent. of this, or 28lb., may be recovered by merely boiling and pounding. The *efficiency* of the Malay method, therefore, amounts to about 2½ per cent. In 1875 the export of gutta from the Straits Settlement and Peninsula was estimated at 10,000,000lb. Accepting these figures as reasonably correct, we must, says Mr. Wray, come to the conclusion that even if we take the amount of gutta wasted at only 30 times the weight of that collected (instead of 37), no less than 300,000,000lb. are wasted in one year, which, at 2s. 6d. per lb., means £37,500,000 worth of gutta thrown away. With the object of testing whether it would be worth while to collect, dry and send home the bark, some specimens were despatched to Kew, and tested by the India-Rubber, Gutta-Percha and Telegraph Works Company, whose chemists reported that there was so much resin present as to render the gum valueless, and that the cost of solvents for the large scale operations that would be necessary made it very improbable that the idea would prove remunerative.

The United States Patent Office.—The following extracts from the report of the United States Commissioner of Patents for the year 1890 may be of interest:—The Patent Office, he says, still awaits a suitable laboratory. The great number of applications for patents relating to metallurgical, chemical, and electrical inventions renders it necessary that a completely-equipped laboratory should be at the services of examiners and applicants for patents. An inconsiderable sum would secure the necessary apparatus and appliances. The model halls now contain about 154,000 models. The number added during the year was 535. The Commissioner regards it as nothing less than a public calamity that the Office has been compelled to suspend the reception of models, excepting in special instances, for want of space in which to store and exhibit them. He hopes that the time will come when models will again be required in connection with all applications. The Patent Office library at present consists of 59,856 volumes. During the year, 1,713 volumes were added. Section 4,904 of the Revised Statutes requires that when an application is made for a patent which, in the opinion of the Commissioner, would interfere with any pending application, or with any unexpired patent, he shall institute proceedings to determine the question of priority of invention. The Commissioner is sorry to add that it is currently believed that in some cases new parties enter the field, not so much to obtain a patent for themselves as to obstruct and postpone the rights of meritorious inventors. In his opinion a law providing that a party prevailing upon the first proceeding shall be permitted to take his patent, and that subsequent applicants shall contest priority with a patentee instead of with an applicant, would be found to constitute a practical remedy for some of the incidental evils of the system as it at present exists. The State in which most patents were granted during 1890 was New York (4,585), Wyoming coming the last on the list with 8. The most actively patenting State was Connecticut, in which 125 patents were taken out per 100,000 inhabitants, as against 4 in Mississippi. The citizens of foreign countries to whom most patents were granted were England (721), Germany (452), and Canada (371). In 1837, 436 patents were issued by the United States office; half a century after, namely, in 1887, the figure was 21,477; in 1890 the total was 26,292. During 1890 no less than 226 patents were granted in connection with electric traction (systems, motors, cars, conduits, trolleys, &c.), in addition to 66 patents for electric motors, in which electric traction was not specifically referred to. The patents for arc lamps and auxiliary apparatus numbered 50, dynamos 100, secondary batteries 98, electric meters 30, conductors and conduits 100, commutators 23, telephones 20, insulators and insulating compounds 57; galvanic batteries claimed 33 patents, and voltaic batteries 1, which was granted to Mr. Edison. Some 12 electric locomotives were patented, together with 4 galvanometers, 5 reciprocating electric engines, 7 magnetic separators 4 electric soldering irons, 9 thermo-electric batteries, 14 electric heaters, and 3 electro-magnetic clutches. Electric welding and metal working by electricity counted 25 patents. The most prolific electrical inventor seems to have been Mr. R. M. Hunter, who took out no less than 39 electric railway patents during 1890.

ELECTROMAGNETIC THEORY.—XXIII.

BY OLIVER HEAVISIDE.

(Continued from page 218.)

§ 115. In the preceding account of vector addition, and of the scalar product and the vector product, the reader has nearly all that is needed for general purposes in geometry and in the usual physical mathematics involving vectors, so far as the algebra itself is concerned. For the addition of differentiations does not usually introduce anything new into the algebra. Thus, in the analysis of varying vectors, we have the same vector algebra with new vectors introduced, these being derived from others by the process of differentiation.

The ideas concerned in the differentiation of a vector with respect to a scalar are essentially the same as in the differentiation of a scalar. Thus, u being a scalar function of x, *i.e.*, a quantity whose value depends on that of x, we know that if Δu is the increment in u corresponding to the increment Δx in x, then the ratio $\Delta u/\Delta x$ usually tends to a definite limiting value when Δx is infinitely reduced, which limit, denoted by du/dx, is called the differential coefficient of u with respect to x. This I should be strongly tempted to call the "differentiant" of u to x, were I not informed on the highest authority that the expression "differentiant" for "differential coefficient" is objectionable. But the differentiating operator d/dx which acts on the operand u may be termed the "differentiator," as has perhaps been done by Sylvester and others. This way of regarding a differential coefficient, splitting du/dx into (d/dx) and u, sometimes leads to great saving of labour, though we are not concerned with it immediately.

The differential coefficient is thus strictly the *rate* of increase of the function with the variable, or the increase of the function per *unit* increase of the variable, on the tacit assumption that the rate of increase of the function keeps the same value throughout the whole unit increment in the variable as it has for the particular value of the variable concerned. This plan, referring to unit increment, is often very useful. The reservation involved, though it must be understood, need not be mentioned.

There is also the method of differentials, which is of some importance in vector analysis, as it can be employed when differential coefficients do not exist. Thus, u being a function of x, whose differential is dx, the corresponding differential of u is

$$du = f(x+dx) - f(x); \quad . \quad . \quad . \quad . \quad (56)$$

which, by expanding $f(x+dx)$, reduces to

$$du = \frac{du}{dx}dx, \quad . \quad . \quad . \quad . \quad . \quad (57)$$

provided we neglect the squares and higher powers of dx, that is, regard dx as infinitesimal, and therefore du also. And if there be two variables, as in $u = f(x, y)$, then we have

$$du = f(x+dx, y+dy) - f(x, y), \quad . \quad . \quad (58)$$

leading to

$$du = \frac{du}{dx}dx + \frac{du}{dy}dy, \quad . \quad . \quad . \quad . \quad . \quad (59)$$

expressing the differential of u in terms of those of x and y.

Now let the operand be a vector function of x, say, $\mathbf{E}$. For instance, x may mean distance measured along a straight line or axis in an electrostatic field, where $\mathbf{E}$, the electric force, will usually change as we pass along the line. It may change continuously in direction as well as in magnitude; that is, the change itself in $\mathbf{E}$ between two points on the line is a vector, being the vector $\Delta\mathbf{E}$ which must be added to the $\mathbf{E}$ at the first point to produce that at the second point. Dividing by Δx, the increment in x, we get the vector $\Delta\mathbf{E}/\Delta x$; and this, when the increments are taken smaller and smaller, approximates towards a definite limiting vector denoted by $d\mathbf{E}/dx$, which is, by the manner of its construction, the rate of increase of $\mathbf{E}$ with x, or the increase in $\mathbf{E}$ per unit increase in x.

We have also, in differentials,

$$d\mathbf{E} = f(x+dx) - f(x), \quad . \quad . \quad . \quad . \quad (60)$$

leading to

$$d\mathbf{E} = \frac{d\mathbf{E}}{dx}dx, \quad . \quad . \quad . \quad . \quad . \quad . \quad (61)$$

understanding that the differentials dx and $d\mathbf{E}$ are infinitesimal.

Similarly, the rate of increase of the vector $d\mathbf{E}/dx$ with x is the second differential coefficient $d^2\mathbf{E}/dx^2$; and so on.

§ 116. In semi-Cartesian form we have

$$\mathbf{E} = \mathbf{i}E_1 + \mathbf{j}E_2 + \mathbf{k}E_3. \quad . \quad . \quad . \quad . \quad (62)$$

Here the scalars E_1, E_2, E_3 are functions of x, whilst the reference vectors $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ are constants; so we have

$$\frac{d\mathbf{E}}{dx} = \mathbf{i}\frac{dE_1}{dx} + \mathbf{j}\frac{dE_2}{dx} + \mathbf{k}\frac{dE_3}{dx}, \quad . \quad . \quad . \quad (63)$$

showing the components of the vector $d\mathbf{E}/dx$.

Similarly,

$$\frac{d^2\mathbf{E}}{dx^2} = \mathbf{i}\frac{d^2E_1}{dx^2} + \mathbf{j}\frac{d^2E_2}{dx^2} + \mathbf{k}\frac{d^2E_3}{dx^2} \quad . \quad . \quad . \quad (64)$$

shows the components of the second differential coefficient, obtained by differentiating (63).

Now, this semi-Cartesian process is quite general. Any vector function may be expressed in the form (62), and when the right member is differentiated, the differentiations are performed upon scalar functions. The same remark applies to (63) and (64), &c.; so we see that the rules for differentiating vectors, and functions of vectors, with respect to scalar variables, are the same as those for differentiating similar functions of scalars, so far as the independent action of a differentiator on the separate members of a product goes.

Thus, in differentiating a scalar product, $\mathbf{AB}$, with respect to a variable scalar, t, we have, by (23),

$$\frac{d}{dt}\mathbf{AB} = \frac{d}{dt}(A_1B_1 + A_2B_2 + A_3B_3)$$

$$= (\dot{A}_1B_1 + \dot{A}_2B_2 + \dot{A}_3B_3) + (A_1\dot{B}_1 + A_2\dot{B}_2 + A_3\dot{B}_3);$$

or, re-transforming to vectors

$$\frac{d}{dt}\mathbf{AB} = \dot{\mathbf{A}}\mathbf{B} + \mathbf{A}\dot{\mathbf{B}}, \quad . \quad . \quad . \quad . \quad . \quad (65)$$

just as if $\mathbf{A}$ and $\mathbf{B}$ were scalars. Similarly, we have

$$\frac{d}{dt}\mathrm{V}\mathbf{AB} = \mathrm{V}\dot{\mathbf{A}}\mathbf{B} + \mathrm{V}\mathbf{A}\dot{\mathbf{B}}, \quad . \quad . \quad . \quad . \quad (66)$$

as we may see immediately by differentiating the semi-Cartesian expansion of $\mathrm{V}\mathbf{AB}$, equation (41). We have also

$$\frac{d}{dt}\mathbf{AVBC} = \dot{\mathbf{A}}\mathrm{V}\mathbf{BC} + \mathbf{A}\mathrm{V}\dot{\mathbf{B}}\mathbf{C} + \mathbf{A}\mathrm{V}\mathbf{B}\dot{\mathbf{C}}, \quad . \quad . \quad . \quad (67)$$

and

$$\frac{d}{dt}\mathrm{V}\mathbf{A}\mathrm{V}\mathbf{BC} = \mathrm{V}\dot{\mathbf{A}}\mathrm{V}\mathbf{BC} + \mathrm{V}\mathbf{A}\mathrm{V}\dot{\mathbf{B}}\mathbf{C} + \mathrm{V}\mathbf{A}\mathrm{V}\mathbf{B}\dot{\mathbf{C}}. \quad . \quad (68)$$

But, although we proceed formally, as in the ordinary differentiation of scalars, as regards the properties peculiar to differentiation, yet we must always remember those which are peculiar to the vector algebra. For example, we must not only on the left sides, but also on the right sides of (67) and (68), remember the reversal of the sign of a vector product with the order of the letters.

Independently of $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$, we may proceed thus, using differentials:—

$$d(\mathbf{AB}) = (\mathbf{A}+d\mathbf{A})(\mathbf{B}+d\mathbf{B}) - \mathbf{AB} = \mathbf{A}d\mathbf{B} + \mathbf{B}d\mathbf{A} \quad . \quad (69)$$

omitting the infinitesimal $d\mathbf{A}\,d\mathbf{B}$ of the second order. Dividing by dt, and proceeding to the limit, we obtain (65).

Similarly we have

$$d(\mathrm{V}\mathbf{AB}) = \mathrm{V}(\mathbf{A}+d\mathbf{A})(\mathbf{B}+d\mathbf{B}) - \mathrm{V}\mathbf{AB} = \mathrm{V}(d\mathbf{A})\mathbf{B} + \mathrm{V}\mathbf{A}d\mathbf{B}. \quad (70)$$

omitting the second differential $\mathrm{V}d\mathbf{A}d\mathbf{B}$. So, dividing by dt, we obtain (66).

In getting (69) we have, of course, used the distributive law of scalar products, equation (17); and, in getting (70), the similar law of vector products, equation (50).

§ 117. Some spacial and motional examples may be here usefully inserted to illustrate the differentiation of vectors. Let there be any curve in space, and let s be length measured along it from some point on the curve. Also let $\mathbf{r}$ be the vector from any fixed origin O to a point P on the curve. We have then $\mathbf{r} = f(s)$. With the form of the function we have no concern.

Now, consider the meaning of the first differential coefficient $d\mathbf{r}/ds$. First, if the increment Δs is finite, say the *arc* PQ, the corresponding increment in $\Delta\mathbf{r}$ is the vector *chord* PQ, the new vector of the curve being OQ, that is $\mathbf{r}+\Delta\mathbf{r}$, instead of OP or $\mathbf{r}$. We see that $\Delta\mathbf{r}/\Delta s$ is a vector parallel to the chord, whose tensor

Digitized by Google

is the ratio of the chord to the arc. Now reduce the increments to nothing. In the limit the direction of $d\mathbf{r}/ds$ is that of the tangent to the curve at P, and its tensor is unity, since the chord and the arc tend to equality. That is,

$$\frac{d\mathbf{r}}{ds}=\mathbf{T}=\mathbf{i}\frac{dx}{ds}+\mathbf{j}\frac{dy}{ds}+\mathbf{k}\frac{dz}{ds}, \quad . \quad . \quad . \quad . \quad (71)$$

where $\mathbf{T}$ is the unit vector tangent, and the semi-Cartesian expression (got by expanding $\mathbf{r}$) is also given. In the figure the size of $\mathbf{T}$ is quite arbitrary, since the unit of length is arbitrary.

Next, differentiate again with respect to s to obtain the second differential coefficient $d^2\mathbf{r}/ds^2$ or $d\mathbf{T}/ds$. It is the change in the unit tangent per unit step along the curve. Now, as the unit tangent cannot change its length, it can only change its direction; and, moreover, this change is a vector perpendicular to the tangent. It and the two tangents, initial and final, are in some plane, usually termed the osculating plane. It is the plane of the curve for the time being, unless it be a plane curve, when it is the plane of the whole curve. Thus $d\mathbf{T}/ds$, being at right angles to $\mathbf{T}$, points from the curve towards the centre of curvature for the time being. Moreover, its tensor measures the curvature. For the usual measure is $d\theta/ds$, where $d\theta$ is the angle between the tangents at the ends of ds, and it may be readily seen that this is the tensor of $d\mathbf{T}/ds$.

Now the reciprocal of the curvature is the radius of curvature. If then $\mathbf{R}$ be the vector from the curve to the centre of curvature C (Fig. 7), we have

$$\frac{d^2\mathbf{r}}{ds^2}=\frac{d\mathbf{T}}{ds}=\frac{1}{\mathbf{R}}, \quad . \quad . \quad . \quad . \quad . \quad (72)$$

and the vector from the origin to the centre of curvature is $\mathbf{r}+\mathbf{R}$.

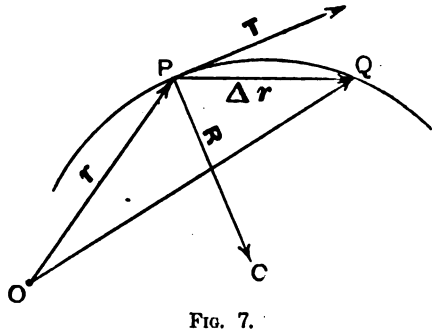

FIG. 7.

Now, referring to the same figure, let a point move along the curved path. Consider its velocity and acceleration, taking t the time for independent variable. We have

$$\frac{d\mathbf{r}}{dt}=\frac{d\mathbf{r}}{ds}\frac{ds}{dt}=v\mathbf{T}=\mathbf{v}, \quad . \quad . \quad . \quad . \quad (73)$$

by using (71), and denoting the velocity by $\mathbf{v}$. Its tensor is v or ds/dt. The interpretation of (73) is sufficiently obvious, since it says that the motion is (momentarily) along the tangent, at speed v.

Differentiate again to t. We get

$$\frac{d\mathbf{r}^2}{dt^2}=\frac{dv}{dt}\mathbf{T}+v\frac{d\mathbf{T}}{dt}. \quad . \quad . \quad . \quad . \quad (74)$$

That is, the vector rate of acceleration is exhibited as the sum of two vectors, the first being the tangential component, whose tensor equals the rate of acceleration of speed, whilst the second we may expand thus, by introducing the intermediate variable s:—

$$v\frac{d\mathbf{T}}{dt}=v\frac{d\mathbf{T}}{ds}\frac{ds}{dt}=\frac{v^2}{\mathbf{R}} \quad . \quad . \quad . \quad . \quad (75)$$

where the third form is got by using (72). This shows the rate of acceleration perpendicular to the motion. It is towards the centre of curvature, of amount v^2/R, the well known result.

§ 118. Again referring to Fig. 7, if the curve be not a plane curve, or be a tortuous curve, the osculating plane undergoes change as we pass along the curve. It turns round the tangent, and the measure of the tortuosity is the amount of turning per unit step along the curve. It is $d\phi/ds$, if $d\phi$ is the angle between the two osculating planes at the extremities of ds. It is equivalently denoted by the tensor of $d\mathbf{N}/ds$, if $\mathbf{N}$ be the unit normal to the osculating plane. This is similar to the equivalence of $d\theta/ds$ and the tensor of $d\mathbf{T}/ds$ in measuring the curvature before noticed, the equivalent plane in that case being the plane normal to $\mathbf{T}$.

The three vectors, $\mathbf{T}$, $\mathbf{N}$, and $\mathbf{R}_1$, form a unit rectangular system, for we have

$$\mathbf{N}=\mathrm{V}\mathbf{T}\mathbf{R}_1, \quad . \quad . \quad . \quad . \quad . \quad . \quad (78)$$

since $\mathbf{T}$ and $\mathbf{R}_1$ are perpendicular unit vectors. As we move along the curve this system of axes moves as a rigid body, since there is no relative change. They may, in fact, be imagined to be three perpendicular axes fixed in a rigid body moving along the curve in such a way that these axes keep always parallel to the $\mathbf{T}$, $\mathbf{R}_1$, and $\mathbf{N}$ of the curve. As it moves, the body rotates. It rotates about the $\mathbf{N}$ axis only when the curve is plane, but about the $\mathbf{T}$ axis as well when tortuous. The vector change (infinitesimal) in $\mathbf{T}$ is perpendicular to it, in the osculating plane—that is, the plane whose normal is $\mathbf{N}$, and is directed towards the centre of curvature. And the vector change (infinitesimal) in $\mathbf{N}$ is perpendicular to it, also in the osculating plane, and directed towards the centre of curvature, the vector $\mathbf{R}$ from the curve to the centre of curvature being on the intersection of the two planes mentioned.

Various expressions for the tortuosity may be obtained. Let it be Y the tensor of $\mathbf{Y}$, given by

$$\mathbf{Y}=\frac{d\mathbf{N}}{ds}=\frac{d}{ds}\mathrm{V}\mathbf{T}\mathbf{R}_1 \quad . \quad . \quad . \quad . \quad . \quad (79)$$

Then, by (78) and the context, (79) gives one expression. A second is got by performing the differentiation, giving

$$\mathbf{Y}=\mathrm{V}\frac{d\mathbf{T}}{ds}\mathbf{R}_1+\mathrm{V}\mathbf{T}\frac{d\mathbf{R}_1}{ds} \quad . \quad . \quad . \quad . \quad (80)$$

But the first term on the right is zero, by (72), the two vectors after V being parallel. So

$$\mathbf{Y}=\mathrm{V}\mathbf{T}\frac{d\mathbf{R}_1}{ds}, \quad . \quad . \quad . \quad . \quad . \quad (81)$$

gives another expression. Or

$$\mathrm{Y}=\mathrm{V}_0\mathbf{T}\frac{d\mathbf{R}_1}{ds}, \quad . \quad . \quad . \quad . \quad . \quad (82)$$

considering the tensor only. But, since $\mathbf{Y}$ is parallel to $\mathbf{R}_1$, we have $\mathbf{Y}\mathbf{R}_1=\mathrm{Y}$; therefore, by (81),

$$\mathrm{Y}=\mathbf{R}_1\mathrm{V}\mathbf{T}\frac{d\mathbf{R}_1}{ds} \quad . \quad . \quad . \quad . \quad . \quad (83)$$

is a third and entirely different expression. That $\mathbf{Y}$ is parallel to $\mathbf{R}_1$ we may prove by (79) and (81). Multiply (79) by $\mathbf{N}$. Then

$$\mathbf{Y}\mathbf{N}=\mathbf{N}\frac{d\mathbf{N}}{ds}=\tfrac{1}{2}\frac{d}{ds}\mathbf{N}^2=0,$$

since $\mathbf{N}^2=1$.

This shows $\mathbf{Y}$ is perpendicular to $\mathbf{N}$. It is also, by (81), perpendicular to $\mathbf{T}$. So its direction is that of $\mathbf{R}_1$.

By the parallelepipedal property (40) we may also write (83) thus,

$$\mathrm{Y}=-\mathbf{T}\mathrm{V}\mathbf{R}_1\frac{d\mathbf{R}_1}{ds} \quad . \quad . \quad . \quad . \quad . \quad . \quad (84)$$

Here again, we may write

$$\frac{d\mathbf{R}_1}{ds}=\frac{d\mathrm{R}}{ds\mathbf{R}}=\frac{1}{\mathbf{R}}\frac{d\mathrm{R}}{ds}+\mathrm{R}\frac{d1}{ds\mathbf{R}} \quad . \quad . \quad . \quad . \quad (85)$$

Substituting this compound vector in (84), we see that the first of the resulting vector products vanishes because $\mathbf{R}_1$ and $\mathbf{R}^{-1}$ are parallel. There is then left

$$\mathrm{Y}=-\mathbf{T}\mathrm{V}\mathbf{R}\frac{d1}{ds\mathbf{R}} \quad . \quad . \quad . \quad . \quad . \quad (86)$$

$$=-\mathrm{R}^2\mathbf{T}\mathrm{V}\frac{d\mathrm{T}d^2\mathrm{T}}{dsds^2}, \quad . \quad . \quad . \quad (87)$$

by (72), or, in terms of r and derivatives,

$$\mathrm{Y}=-\mathrm{R}^2\frac{d\mathbf{r}}{ds}\mathrm{V}\frac{d^2\mathbf{r}d^3\mathbf{r}}{ds^2ds^3}, \quad . \quad . \quad . \quad . \quad (88)$$

which is a known symmetrical form, but whose meaning is less easy to understand than several preceding expressions.

Digitized by Google

Since, by the definition of a vector product we have $V_0\mathbf{a}_1\mathbf{b} = b$ when $\mathbf{a}_1$ and $\mathbf{b}$ are perpendicular, $\mathbf{a}_1$ being a unit and $\mathbf{b}$ any vector, we may, from the first equation (79) conclude that

$$Y = V_0 N \frac{dN}{ds}, \quad . \quad . \quad . \quad . \quad . \quad (89)$$

which is equivalent to a form given by Thomson and Tait.

Similarly, $$Y = V_0 T \frac{dN}{ds}, \quad . \quad . \quad . \quad . \quad . \quad (90)$$

Y being perpendicular to T as well as to N.

The reader may, perhaps, find the above relating to tortuosity hard to follow, though the previous matter relating to tangency, curvature, velocity, and acceleration may be sufficiently plain. The hardness lies in the intrinsic nature of tortuosity, as to which see works on analytical geometry. But the reader who wishes to get a sound working knowledge of vectors should go through the ordinary Cartesian investigations, and turn into vectors. Also, convert the above to Cartesian form through i, j, k, and verify all the results, or correct them, as the case may be. Space is too short here for much detail.

(To be continued.)

THE RECENT PARSON'S STEAM TURBINE TRIALS.

We have received a copy of an important letter which Prof. Garnett has sent to Prof. Ewing with regard to the latter's recently published report (*The Electrician*, January 8th, p. 254) on the Parsons Steam Turbine. As the question of the error caused by current lag was first raised in these columns, we have thought it worth while to print Prof. Garnett's communication *in extenso*. A difference of 5 per cent. between the true and the apparent watts is not an altogether negligible quantity, and makes the steam consumption per E.H.P. hour at full load more nearly 28·2 than 27·6lb.

[COPY.]

The Durham College of Science, Newcastle-upon-Tyne,
January 25, 1892.

MY DEAR EWING: My attention has been called to some questions which have been raised respecting the effect of retardation of currents phase upon the output of the steam turbine which you tested in Newcastle a few weeks ago. To determine the magnitude of the error thus caused, two sets of experiments were made, the former by Mr. Parsons and Mr. Stoney, the latter by Mr. Stoney and myself. In these experiments the coils used by you were compared with the water in a section of the cooling pond. The 1,000-volt armature was used, and iron pipes were thrust into the cooling pond to serve as electrodes, so that, in comparison with the 1,000 volts, the E.M.F. due to electrolysis was quite negligible, as was also any change of phase which it could produce.

In order to secure the same number of true watts as the output of the alternator, the valve which gives the intermittent steam admission was blocked open, and the steam was throttled by hand. In the second set of experiments the steam pressure at the point of admission to the cylinder was kept constant at 62lb, and the resistance was so arranged as to keep the volts the same with the coils as with the water resistance. A variation of pressure of 1lb. corresponds to about 1½ units per hour in the output. The volts being the same, and the resistance of the armature practically negligible, it follows that the speed must have been the same, and, the speed and steam pressure being the same, its steam consumption and therefore the output must have been the same, unless the steam had the intelligence to know what was going on in the external circuit and the perversity to modify its conduct for the purpose of leading us astray. The result of this test was that, with the same speed and the same steam pressure, the product of Siemens and Cardew gave 49·5 for the water and 52 for the iron, showing an error of 5 per cent. due to the lag in the iron.

In the other set of experiments the volts were kept the same, but the steam pressure, as well as the amperes, were allowed to vary, two sets of observations being made upon the coils, one with a greater and the other with a less output than in the case of the water. Repeated observations of the relation between the steam pressure and the load have enabled the law of variation of the one with the other to be accurately known, and it was, therefore, easy to interpolate between the two observations with the coils, and to determine the apparent watts which would have been registered with the coils at the pressure used in the water experiment. The result of this interpolation showed that the product of Siemens and Cardew was 4·7 per cent. greater than the true watts.

I hope that before long it will be possible to make a test of the turbine at the full working pressure of 140lb., and with a boiler of sufficient capacity to give fairly dry steam at full load. It was scarcely fair to the turbine to remove its high-pressure rings.—Very sincerely yours,

(Signed) WM. GARNETT.

To Professor J. A. Ewing, M.A., F.R.S., &c.

THE LAUFFEN-FRANKFORT TRANSMISSION EXPERIMENTS.

The *Frankfurter Zeitung*, in expressing the general wish for the speedy publication of the report on the Lauffen-Frankfort transmission experiments, remarks that the long silence of the Commission has been commented upon by adversaries of the system adopted. In the meantime, therefore, the following particulars, which have been obtained by the *Schweizerisch Bauzeitung*, from Herr Emil Huber, of the Oerlikon Works, will be read with interest.

The transmission, says the latter paper, was effected for the most part at a pressure of 16,000 volts, which was only raised towards the close of the tests to 30,000 volts. The early apprehensions that the insulators would not be able to stand this pressure have turned out to be perfectly groundless, as only one insulator, and that at the maximum pressure, was perforated by the stress. Slight breakdowns occurred also in two other instances, on one occasion through the failure of a wire, and on the other owing to the breaking of an insulator. From an examination of the broken surface of this insulator it was clear that the accident was due to a defect in manufacture, which was further corroborated by the fracture of several of them whilst they were being put up.

It is noteworthy that these defective insulators were all of the large type, with the triple oil groove, whilst not one of the small ones with the single groove (which were only used as a makeshift) was found to fail. The larger ones were made in great haste, so that slight faults might easily have escaped notice. It follows accordingly that adequate insulation for such an undertaking can be obtained by simple means and at a reasonable cost. The actual capital outlay per effective horse-power amounted to £60, of which £50 had to be devoted to the conductor.

The question is what proportion of the work absorbed at Lauffen was recovered at Frankfort. Observations were taken simultaneously at Lauffen and Frankfort. At Lauffen currents of 500, 490, and 500 amperes in the three branches were observed, whilst there were 54 volts between each of the leads and the neutral point. Leaving out of the question the phase difference between volts and current, the energy supplied amounted to 80,500 watts. At the same instant 1,060 glow lamps of 16 c.p., or their equivalent, requiring 58,000 watts, were being run off the transformers at Frankfort. This gives an efficiency of 72 per cent. Practically the efficiency must have exceeded this value, probably by about 5 per cent.

The damp weather did not seem to do any harm; no direct leakage to earth could be observed.

The static charge effects occasioned only the smallest loss. In fact, the whole undertaking showed nothing abnormal

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

FRIDAY, January 29th (to-night).

ROYAL INSTITUTION

9 p.m. Evening Discourse. "Tales of the Scottish Peasantry." By Sir George Douglas, M.A.

SPECIAL NOTICE.

A fine Steel Plate Portrait of Prof. W. E. AYRTON, F.R.S., President of the Institution of Electrical Engineers, will be issued with the next number of "THE ELECTRICIAN."

ELECTROTECHNICS.

THE Presidential Address of Prof. AYRTON, although delivered before the Institution of Electrical Engineers, deserves the careful attention of a much wider circle, and should be studied both by those who spend money on the endowment of technical schools and colleges, and by those who spend their time as teachers in such institutions. The address will come as a pleasant surprise to some of our readers, and should be appreciated by all; for, if we may judge of the real aims and results of Prof. AYRTON'S administration, by the objects which he advocates, and the ideals which he contemplates, the Central Institution is doing a more important work than many are aware of. The title is a good one, since the Address deals with a subject that has been miscalled Technical Education. We have recently alluded to the confusion between education and instruction; and while there are many who, like Prof. HUXLEY, urge that the study of science has a high educational value, we either fail to appreciate the sense in which they use the words "science" and "education," or we must be content to differ from their views. The value of "the scientific habit of mind" is too little recognised, it is true; and we take it for granted, that, as Prof. HUXLEY has said, "the diffusion of thorough scientific education is an absolutely essential condition of industrial progress." But industrial progress is not synonymous with culture, and it is brought about by something other than education.

The recognition of the two classes into which workmen may be divided is an important feature in Prof. AYRTON'S address, and marks a liberal view which should not be lost sight of. For the mere machine-minder no "technical education is necessary;" and "his activity, if any is left him after a hard day's work, had probably better be spent in effort

Digitized by Google

of a higher and more recreative character than would alone be necessary to make him a higher class of artisan." For him a varied course of instruction, including violin playing, modelling in clay, an ambulance class, the piano, botany, sanitary science, reading books, and other pursuits are suggested. "His general interests will be roused, the human side of his nature developed, and during the evening, at any rate, he may forget that he is the Slave of the Gramme Ring or the Slave of the Electric Lamp." Thoroughly as we agree with these opinions, we do not like the use of the words "technical education" in this extract, for it is mere instruction that is being discussed, and, curiously enough, the word "instruction" is used to include those subjects which really possess a humanising value. For the other class of workman, who has to use his brains, and on whose wits and ingenuity demands are often made, technical instruction of some sort is indispensable, and a sound knowledge of the elementary scientific principles of his work will enable him to do that work not only intelligently, but well.

Although we cannot altogether agree with the opinions expressed by Prof. HUXLEY in his address on "Science and Culture," from which we have already quoted, there are many other passages which, without being violently torn from their context, may be adduced to support our views. MATTHEW ARNOLD tells us, says Prof. HUXLEY, "that the meaning of culture is 'to know the best that has been thought and said in the world.' It is the criticism of life contained in literature. . . . . Culture certainly means something quite different from learning or technical skill. . . . . Perfect culture should supply a complete theory of life, based upon a clear knowledge alike of its possibilities and of its limitations. We may agree to all this, and yet strongly dissent from the assumption that literature alone is competent to supply this knowledge." Prof. HUXLEY goes on to advocate the introduction of physical science; but we side with Prof. AYRTON in the encouragement of those arts and humanising pursuits of which he has given examples. While a large number of our readers probably take a greater interest in physical science than in any other branch of knowledge, most of them will admit that, *in their own experience*, it has only a secondary educational value. "Higher education" is a rather vague term; it often differs not only in degree but in kind from education proper, and this difference of kind is due to the introduction of technical or scientific instruction, which has nothing in common with education, except that it is imparted by teachers to students. So far from "drawing out" and developing the human side of the human being, mere scientific study and scientific research often appear to dry up sympathy and to narrow intellectual views. We do not for a moment undervalue the immense importance of scientific or technical instruction, study, and research, but only suggest that it should not be confounded with education and culture. By recognising this distinction, specialisation, which is every day assuming greater importance as a factor of success, will no longer be unpopular.

An even greater responsibility rests with those who are engaged in training instructors than with those who are giving technical instruction to students who intend to enter the engineering profession; and it is very satisfactory to learn that the importance of practical experience at the bench is insisted on no less for instructors than for students. The business of a technical instructor is not to act schoolmaster trying to teach a trade; but to be a teacher of theory and its applications, with a practical knowledge of how those applications are made. Pure science is in the triumphant position that the range of the subject is continually increasing. The professor himself is more ignorant of the subjects which he will be teaching five years hence than the student is of the lessons which he will learn five weeks hence. The science master need never be placed in the difficulty in which the classical schoolmaster finds himself, starting boys at ten years old and letting them absorb bit by bit of grammar and syntax, translation and composition, knowing that after eight or nine years the intelligent ones will know all he has, or ever will have, to impart; and conscious that a Girton girl can cram up and pass an examination of fifth-form standard in almost as many weeks. This, not their uselessness, is the real cause of complaint against the classics.

Still more must Prof. AYRTON and those associated with him both at the Central Institution and at Finsbury, and at other establishments of the same character, rejoice that they are not subjected to the evils of "payment by results," with the attendant vices of cramming and cast-iron examination systems. We may lament that larger buildings and better equipped laboratories may be found in other countries; but nowhere are more zealous professors, painstaking demonstrators, and interested, hardworking students to be found than in those of our own institutions in which instruction is given in Electrotechnics.

INSTITUTION OF ELECTRICAL ENGINEERS.

PRESIDENTIAL ADDRESS OF PROFESSOR W. E. AYRTON, F.R.S.

Electrotechnics.

I beg to thank you for the great honour you have done me by electing me as your President for this year, a year which the need for a new complete index of this society's Journal marks out as closing the second decade of its life, a year which sees the second thousand added to our roll of members, and a year which the Electrical Exhibition at the Crystal Palace distinguishes as inaugurating the second decade of electric lighting in Great Britain.

It has gradually become the custom for your incoming President to select as the subject for his Address some investigation that has been engaging his attention. Following this custom I purpose to-night to discuss an experiment in which for the last nineteen years I have taken some part, an experiment which of all others has been the one which I have had most at heart, and that is how best to train the young electrical engineer.

To some it may appear that I am treading on well worn ground; but as the problem is one that is as yet by no means solved, and as it involves the preparation of the machine that is daily used alike by the dynamo constructor, the cable manufacturer, the central-station engineer, and the lamp maker, viz., the human machine, the problem of fashioning this tool so that it may possess sharpness, an even temper, moral strength, and a mental grain capable of taking a high polish, is one that in truth deeply concerns every member, every associate, every student of this society.

It is only fifteen years ago since I wrote from Japan to my old and valued master, Dr. Hirst, then the Principal of the Royal Naval College, Greenwich, asking whether he thought that the time had come for starting in this country a course of Applied Physics somewhat on the lines of that given at the Imperial College of Engineering in Japan. He replied that England was not yet ripe for such an innovation, an opinion which appeared to be borne out by the fact that after the authorities at University College, London, had in 1878 actually advertised for applications for a new chair of "Technology," they decided that it would be premature to take the responsibility of creating such a professorship.

But matters were advancing more rapidly than was imagined by collegiate bodies; for in that same year this most valuable report on Techical Education which I hold in my hand was issued by a committee of the Livery Companies of London, based on the opinions expressed by Sir W. (now Lord) Armstrong, Mr. G. C. T. Bartley, Colonel (now General) Donelly,

Digitized by Google

Captain (now Sir Douglas) Galton, Professor Huxley, and Mr. (now Sir H. Truman) Wood. And although it is twelve years since this book was published I can recommend it to your notice, for it supplies most interesting reading even at the present day.

Under the guidance of the three joint honorary secretaries, Mr. John Watney, Mr. Sawyer, and Mr. (now Sir Owen) Roberts, the City and Guilds of London Institute for the Advancement of Technical Education started with a name that was very long, but in a way that was very modest, to develop a "Trades School," in accordance with this report. They borrowed some rooms, but for use in the evening only, from the Middle Class Schools in Cowper-street, Finsbury, and decided to ultimately erect a chemical laboratory in that neighbourhood. But neither the building of a physical nor even of a mechanical laboratory formed any part of the scheme for this "Local Trades School," for at that time the teaching of the practical applications of physics to industry hardly existed, and certainly not its application to any electrical industry other than telegraphy. To make a start, however, in such teaching was most desirable; and therefore Dr. Wormell, the enlightened head master of the Cowper-street Schools, consented to give up the use of some rooms, not merely during the evening, but also during the day, to enable Dr. Armstrong and myself to carry out our plan of fitting up students' laboratories with a small amount of apparatus kept permanently ready in position.

For the devotion of these rooms to the carrying out of this new experiment we must always feel grateful to Dr. Wormell, for it was necessarily accompanied by a reduction in the size of his school, and consequently by a pecuniary loss to himself.

The first laboratory course of the City and Guilds Institute was then advertised, and, on January 9th, 1880, three students presented themselves, a little boy, a grey-haired lame man, and a middle-aged workman, with emphatic but hazy notions about the electric fluid.

In order to further utilise these rooms the Institute sanctioned laboratory teaching during the day, and one of the cellars of the Cowper-street Schools was borrowed in order to fit up a gas engine, coned shafting, and a transmission dynamometer obtained out of the funds of the Institute; an A Gramme dynamo lent by Mr. Sennett, then one of the students; and two arc-light dynamos lent for transmission of power experiment by the Anglo-American Brush Corporation, whose cordial interest in the work of the City and Guilds Institute has been marked throughout. And as those dynamos were used not for electric lighting, but as laboratory instruments for educational purposes, England can claim to have been one of the first in the field of teaching electrotechnics.

Rapidly grew these electrotechnical classes; soon the temporary laboratories in Cowper-street were overcrowded, especially as applied mathematics and mechanics under Professor Perry were added to the subjects taught. The £3,000 which had been set aside for the building of this "Local Trades School" grew into £35,000, thanks to the combined donations of the Drapers' Company and of the Institute, and in 1881 was laid the foundation stone of the present Finsbury College.

During the many years that Professor Perry and I were linked together, the work of either was the work of both; but now I wish to take this opportunity of acknowledging my personal debt of gratitude for the fund of suggestion which he put forth regarding the teaching of science through its practical applications—the keynote of true technical education. The value of these suggestions you will fully appreciate, for they form the basis of those characteristic and attractive lectures which must be familiar to so many of you who have been his pupils.

As we have seen, then, the present Finsbury College grew out of the "Local Trades School," and formed no part of the original scheme of the Institute. And it was because London was really in want of practical laboratory teaching about dynamos, motors, electric lamps and engines, and because that want was supplied in a form suitable to the comprehension and to the pockets of workmen in the basement and cellars of the Cowper-street Schools, and last, but by no means least, because one of the Executive Committee of the Institute, Mr. Robins, strenuously exerted himself to further technical education in Finsbury, that the various electrical, physical and mechanical laboratories now in Leonard-street came into existence.

But the establishment of a Central Technical Institution "for training technical teachers and providing instruction for advanced students in Applied Art and Science" had been recommended in all the reports sent in to the Committee of the Livery Companies by the six authorities to whom I have referred. So that in the same year that the foundation stone of the Finsbury College was laid by the late Duke of Albany that of the Central Technical Institution was laid by the Prince of Wales.

And if you will allow me to say so, the success of the latter Institution has been no less marked than that of the former; for, in spite of the rather stiff entrance examination, the number of students who attend all four of the departments at the Central Institution is more than threefold what it was five years ago. In fact, in the mechanical and electrical engineering departments there are already about as many students under instruction as the class room and laboratory accommodation will admit. Hence this year will see a considerable increase in the amount of apparatus and machinery, as well as in the space devoted to dynamos and motors in Exhibition-road.

While on the one hand the rapid growth of the work of the Guilds Institute is no little due to the fact that the latter end of this century has ushered in the electric age of the world, the electrical industry of our country on the other hand is no little indebted to the aid so generously given by our City Companies to the teaching of electrotechnics. For the students who during the last eleven years have, for an almost nominal fee, worked in the electrical laboratories at Cowper-street, at the Finsbury College, and at the Central Institution, number several thousands; and nearly every electrical Works, every place giving electrotechnical instruction throughout this country, employs some of them.

The success which these students have thus achieved through their own ability and exertions is, I think, in no small measure due to the Institute having so wisely left the teaching it gave untrammelled by any outside examining body, so that it was possible for this teaching to be directed solely to the professional needs of the students, to be modified from time to time as it seemed necessary.

My hearty thanks are, indeed, due to the Japanese Government and the City and Guilds Institute, my masters during the last nineteen years, for having left my colleagues and myself unfettered liberty to carry on this experiment of finding out better and better ways of teaching the applications of science to industry.

And there need be no fear that with this freedom the teaching will become stereotyped, and gradually cease to deal with the living science of the factory; for, being bound by no code, we are able to vary our methods, our experiments, and our apparatus according to the continually changing conditions of the profession. In order that the Guilds Institute should fulfil its aim, it is absolutely necessary that its teaching should keep pace with industrial progress. Now, even if it were possible for outside examiners, with fixed scholastic notions, to aid in securing this result, would not their efforts be superfluous; for are there not *you*, the employers of labour, to ultimately decide whether the human tool we fashion is, or is not, adapted to your requirements?

Leaving now the consideration of the direct work of the City and Guilds Institute, including their extended system of technological examinations, at which last year 7,322 candidates were examined in 53 different subjects at 245 different places in Great Britain and the Colonies, the indirect results that have proceeded from the initiative of this Institute are even greater. For while twelve years ago education in applied science in this country was a tender little infant requiring careful watching and support, combined with constant encouragement, to-day Technical Education—with a capital T and a capital E, bear in mind—is a stalwart athlete, the strong man on the political platform, exercising the minds of County Councillors, and actually regarded as of more importance than the vested interests of the publican.

Digitized by Google

Until quite recently it was the technical education of the young engineer that had to be considered; but now the problem has become a far wider one, for the education of the British workman is being vigorously pushed forward, and I think that it has become incumbent on you—the representatives of the electrical profession—to express your decided opinion as to what this education of the electrical artisan ought to be.

The technical education snowball, set in motion twelve years ago by the City companies, has been rolling—nay, bounding forward—so swiftly during the last year or two, that probably some of you have hardly followed it in its rapid growth both in size and speed. £30,000 has been spent on the Polytechnic in the Borough-road, the Charity Commissioners have already endowed the school with an income of £2,500 a year, and it is hoped that before the building is opened this year the income will have been doubled. £50,000 has been already promised for the Battersea Polytechnic, the Charity Commissioners having also undertaken to provide this technical school with an income of £2,500 a year as soon as the subscription reaches £60,000; and for the establishment of a Polytechnic in the City £50,000 has been set aside out of the funds of the Charity Commissioners, as well as a yearly grant of £5,350. Finally, not to speak of polytechnics in north, south, east, and west London, Mr. Quinton Hogg has himself spent over £100,000 on the Regent-street Polytechnic, while the Drapers' Company have alone given £55,000 to the technical department of the People's Palace at Mile End, and endowed it with an income of £7,000 a year; and, most recently of all, the Goldsmiths' Company have put on one side nearly a quarter of a million sterling out of their property for the land, the buildings, and for an endowment of £5,000 year in perpetuity for their Technical and Recreative Institute recently opened at New Cross.

The following table gives an idea of the sort of sums that are being spent on polytechnic education in London, but it does not profess to give the entire amounts that have been devoted to capital expenditure and yearly maintenance, even for the six Polytechnics named in the table.

CAPITAL EXPENDITURE.		YEARLY ENDOWMENTS.	
POLYTECHNIC, BOROUGH ROAD.			
Already spent	£30,000	Charity Commissioners alone (Endowment expected to be doubled before opening).	£2,500
BATTERSEA POLYTECHNIC.			
Already subscribed	50,000	Charity Commissioners alone	2,500
CITY POLYTECHNIC.			
Charity Commissioners alone to spend	50,000	Charity Commissioners alone	5,350
REGENT-STREET POLYTECHNIC.			
Spent by Mr. Quintin Hogg	100,000	Charity Commissioners alone	3,500
„ Charity Commissioners	11,750		
PEOPLE'S PALACE, MILE END.			
Given by Drapers' Company alone	55,000	Drapers' Company alone.....	7,000
		Charity Commissioners alone	3,500
Given by Charity Commissioners alone	6,750		
TECHNICAL AND RECREATIVE INSTITUTE, NEW CROSS.			
Given by Goldsmiths' Company	70,000	Goldsmiths' Company	5,000
(Representing a total expenditure at New Cross of nearly £250,000.)			
Other contributions to Polytechnics in London by Charity Commissioners	6,000	Yearly endowments of Charity Commissioners to other Technical Institutions in London...	3,200
TOTALS FROM THE ABOVE SOURCES ALONE.			
	£379,500		£32,500

Large as are these sums, they are, however, small compared with the amount raised by Mr. Goschen's beer and spirit tax, which it has been decided shall be used for the public benefit, and not for the benefit of the publican. The counties and county boroughs of England now receive nearly three-quarters of a million sterling per annum, of which the whole may be devoted to technical education. The majority of the counties and county boroughs propose to take advantage of this magnificent opportunity, and spend on technical education the entire sum allocated to them, while the remainder use at least a part for this purpose. Middlesex and London, however, stand alone, and employ their whole yearly grant of £163,000 for the relief of the rates, on the plea that they consider that the City companies are well able to look after the technical education of the metropolis.

In addition to this beer and spirit duty, 106 towns are levying rates in aid of technical education under the Technical Instruction Acts of 1889 and 1891, the number of these towns having increased by 20 in the last seven months, showing how rapidly is this desire for technical education spreading throughout Great Britain.

In addition to the large sums contributed for technical education by the City companies, collegiate bodies, and private persons who have the practical education of the nation at heart, the following represents, as far as I have been able to ascertain, the amounts that it has been already decided shall be *actually* spent *yearly* on technical education in England alone, exclusive of Scotland, Ireland and Wales:—

Received from the Customs and Excise Duties	**£500,000**
„ „ Rates	**18,046**
Given by the Charity Commissioners	**20,550**
	£538,596

The yearly amount that will be actually raised under the Technical Instruction Acts will be far larger than the £18,046 stated above, for this represents only the sums of the amounts raised in the very few towns who have already made returns.

Hence the total sum to be actually spent in England alone on so-called technical education certainly exceeds £600,000 per annum.

The teaching of electrical technology has been started in some form or other in nearly every important town in Great Britain; therefore there is no occasion for me to advocate, as I did in this room ten years ago, that a student of electrical engineering should have an education in applied science; but what I desire to most strenuously urge on you to-night is that it is your bounden duty to see that some portion of the vast sum that is about to be spent on the education of the people is used to give such a training to your workmen as shall really benefit your industry. For otherwise there is great fear that most of the money devoted to electrical teaching will either be frittered away on the natural-loadstone rubbed-amber-order of instruction so dear to the hearts of the schoolmen, or on semi-popular lectures describing in a bewilderingly sketchy fashion the whole vast field of electrical engineering.

The workmen you employ are of two classes. In the one class is the man who is all day long, say, stamping out iron discs for armature cores, and the boy who, say, feeds the screw-making machine with its proper meals of brass rod. For such work no technical education is necessary; the workers are mere adjuncts to the machines to be dispensed with as the machines become more and more perfect. Hence, unless the machine-minder has the ambition and the ability to rise to some less mechanical occupation, his activity, if any is left him after a hard day's work, had probably better be spent in effort of a lighter and more recreative character than would alone be necessary to make him a higher class of artisan.

For him the Polytechnic variety course of instruction is an inestimable blessing, for he can do a little typewriting, learn violin playing and modelling in clay, attend an ambulance class, recite a poem, and devote the remainder of his leisure to the piano, botany, sanitary science, reading books, and learning how to keep them.

His general interests will be roused, the human side of his nature developed, and during the evening, at any rate, he may forget that he is the slave of the Gramme ring or the slave of the electric lamp.

No wonder, then, that within two months of the opening of the Goldsmiths' Institute, at New Cross last autumn, 4,000 members were enrolled.

But your workman of the other class must, or at any rate ought to, think. Take for example the man engaged in wiring houses, whose work is continually changing and offering small problems to be solved. Here common sense—or uncommon sense if you prefer it—is of great value, and the work to be good *must* be

Digitized by Google

done by a man with a knowledge of principles, and not by a mere machine-minder.

Many joints—bad joints; wires laid in cement under mosaic which cannot be replaced except at vast expense, even although the insulation has rotted away; parqueterie floors nailed to insulated wire; switch boards screwed on to damp walls; lamp holders that only make contact when the lamps are twisted askew; high-class insulated mains terminating in snake-like coils of flexible wire rubbing against metal in shop windows under shop fronts; heavy oriental metal lamps hanging from lightly insulated cord—all this would be avoided if the workmen had been taught to use their brains as well as their hands.

Now, do you think that the teaching necessary for this purpose is likely to be given at the ordinary English Polytechnic School? In the case of the Goldsmiths' Institute, the electrotechnical department has been put under the charge of Messrs. Dykes and Thornton, two diploma students of the Central Institution; and the fact that these two men are, in addition, both employed in Messrs. Siemens' Works, at Charlton, leads one to hope that their teaching, at any rate, will breathe the spirit of the factory; and, therefore, if ample funds be forthcoming for keeping the apparatus at New Cross always up to date, so that the meters, the models, the dynamos—not merely now at the start, but three years hence, six years hence—are truly representative of the industry, there will be a fair prospect that the electrical department of the Goldsmiths' Institute, although but a fraction of the whole undertaking, may really benefit the electrical workmen in the east end of London.

(To be continued.)

THE HARMONIC ANALYSIS OF TRANSFORMER CURVES.*

BY DR. J. A. FLEMING, M.A.

(Concluded from page 296.)

§ 2. **Curves of Magnetic Induction and Leakage.** — The observed curves of current and electromotive force give us the means of determining other curves which will represent the variation of the magnetic induction in the core. The induction density is not necessarily and not generally the same in all parts of the core. If, at any instant, t, b_1 and b_2 represent the number of lines of force, commonly so called, which are linked with the primary and secondary circuits respectively, and if B_1 and B_2 are the maximum values of these quantities, then B_1 and B_2 are called the total inductions through the primary and secondary circuits. B_1 has not the same value as B_2 when the secondary circuit is loaded, because some lines of force which are linked with the primary circuit escape passing through the secondary, and this constitutes the magnetic leakage of the core. It is also generally the case that the inductive density is not the same in all parts of the cross section of the iron core. Let B_1, B_2, however, be the mean value of the lines *per square centimetre* of cross section of the core. If S is the area of cross section of the iron core or magnetic circuit, and if N_1 is the number of windings of the primary coil, then $N_1 S B_1$ will be the maximum total induction in C.G.S. units enclosed by the primary or will be the maximum of the total number of lines of force linked with the primary circuit. Let b_1 be as stated, the instantaneous value of B_1. Then $N_1 S \frac{d b_1}{d t}$ will express the time rate of change of b_1 at any instant, and will, therefore, be the back-electromotive force induced at that instant in the primary circuit. Hence, by the fundamental equation

$$N_1 S \frac{d b_1}{d t} + r i_1 = e_1.$$

In which equation r stands for the ohmic resistance of the primary circuit, and i_1 and e_1 the instantaneous values of the primary current and impressed electromotive force at the same instant, when the secondary circuit is open. Therefore we have

$$\frac{d b_1}{d t} = \frac{e_1 - r i_1}{N_1 S};$$

and therefore $b_1 = \int_{b_1=0}^{b_1=b_1} \frac{e_1 - r i_1}{N_1 S} d t + \text{const.}$

where the integral is taken between proper limits. This equation shows us that if we have the curve for e_1 and the curve for i_1 we can construct a curve corresponding to $e_1 - r i_1$, and by integrating the area of this last curve between limits can obtain the value of the magnetic induction enclosed by the primary circuit at the instant corresponding to any value of e_1 and i_1. It is obvious that when $r i_1 = e_1$ then $\frac{d b_1}{d t} = o$, and hence this point corresponds to the maximum positive or negative value of the induction B_1.

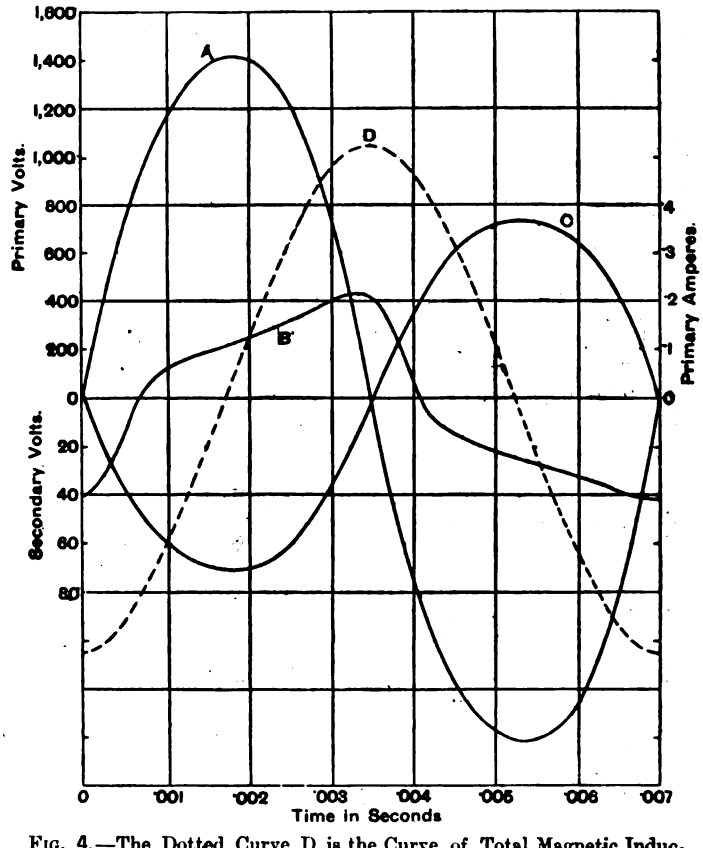

FIG. 4.—The Dotted Curve D is the Curve of Total Magnetic Induction in the Core of the 10-Light Westinghouse Transformer calculated from the Curves of Primary Electromotive Force (A) and Current (B). One scale division (vertical) = 100,000 Lines (C.G.S.) = ·001 Gauss.

Again, if B_2 stands for the average value of the magnetic induction within the secondary circuit, or for the average number of lines of force per square centimetre, which are linked with the secondary circuit, and if b_2 stands for the instantaneous value of the same, then the instantaneous value of the secondary electromotive force e_2 is

$$e_2 = N_2 S \frac{d b_2}{d t}.$$

Where N_2 is the number of secondary windings and S the cross section of the magnetic circuit, it follows that

$$b_2 = \int \frac{e_2}{N_2 S} d t + \text{const.}$$

And the instantaneous value of the induction through the secondary circuit at any instant can be obtained by integrating the curve of secondary electromotive force between proper limits (see Fig. 4). In general b_1 is not identical with b_2, and the curves of induction so formed are not similar. This is because magnetic leakage intervenes to cause the induction through the

* These articles form part of Vol. II. of "The Alternate Current Transformers in Theory and Practice." All rights reserved.

Digitized by Google

secondary circuit to be less than the induction through the primary circuit, that is to say, all the lines of force which are linked with the primary are not linked with the secondary circuit. The difference between b_1 and b_2 being taken, gives us the curve of magnetic leakage. In Fig. 5 the curve F, representing b_1, is so deduced from the primary electromotive force, and the curve G, representing b_2, is deduced from the curve of secondary electromotive force. The curve H represents the curve of magnetic leakage. The ordinates of the curve H are obtained by taking the difference of those of curves F and G.

The student will find it an assistance to adopt a suggestion which has already been made of giving a name to a unit of magnetic induction equal to 10^8 "lines of magnetic force." This quantity it has been proposed to call *one gauss*. The gauss, therefore, is a unit in which magnetic induction is measured. The common custom which we have hitherto followed is to employ the term *the magnetic induction* to denote that which ought properly to be called *the density of magnetic induction*. This necessitates the use of the phrase *total induction*, to denote the whole number of so-called lines of force passing through any

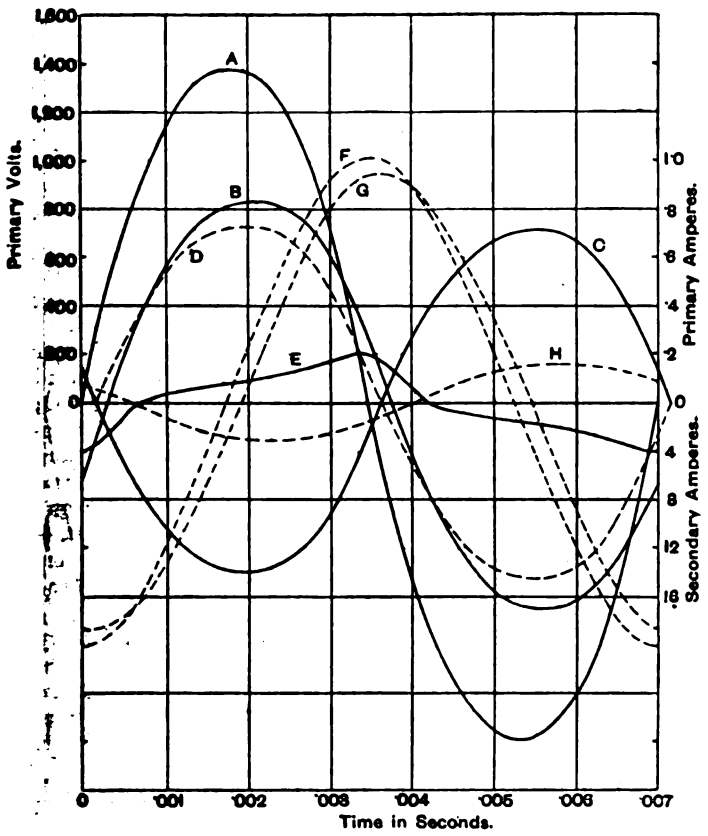

FIG. 5.—Transformer Diagram for 10-Light Westinghouse Transformer. A = Primary E.M.F. ; B = Primary Current ; F = Induction through Primary ; G = Induction through Secondary ; H = Magnetic Leakage Curve E = Magnetising Component of Primary ; C = Secondary Current.

area and to distinguish it from the number passing through a unit of area taken perpendicularly to those lines. The simplest plan is to adopt the word *gauss* as the name for a certain amount of magnetic induction or for 10^8 lines of magnetic force. We can then speak of an induction, meaning a total induction of so many *gausses*, through any area, and, if we wish to refer to the induction density, or *the* induction, at any point, we can do so by speaking of the *gausses* per square centimetre at that point. In the above equations if e and i are measured in volts and amperes, b is determined in gausses, and can always be converted to C.-G.-S. measure by multiplication by 10^8.

THE WORK OF JOSEPH HENRY.

In the New York *Electrical Engineer* for January 13th appears the first of a series of articles, entitled "America's Part in the Discovery of Magneto-Electricity—A Study of the Work of Faraday and Henry." These articles are from the pen of Miss Mary A. Henry, and form a vindication of her father's claims to the independent discovery of magneto-electricity, and other phenomena of scarcely less importance. The invaluable researches of Joseph Henry, Professor of Mathematics and Natural Philosophy at Albany Academy, are now in no danger of being overlooked ; powerful advocates of his scientific claims are not confined to the ranks of his admiring countrymen. "It detracts nothing from Henry's independent and original discovery of the law of relation between the 'electric flow' and the 'electric resistance,'" says his daughter, "that Ohm, in far distant Munich, had a theoretical dream of such a law, which, with a sagacity little short of marvellous, he reduced to a concrete mathematical formula." It does not, indeed. Many of us, however (like the political economists of old in regard to wealth), are inclined to consider fame as a fixed quantity, of which one man can only secure a fragment at the expense of another. It is to the imperishable credit of Henry that he lighted upon magneto-electricity notwithstanding multitudinous difficulties and disadvantages ; but Faraday's independent discovery of it is in no way *discredited* thereby. A priority of a few days, or it may be of a few weeks or months, is of comparatively small moment. Pure research should be the highest of intellectual pursuits, and not a mere race.

We give below a few extracts from Miss Henry's article, not because they contain any fresh evidence in support of her father's title to scientific immortality, but because they state the pathetic facts of the case concisely, clearly, and calmly :—

"There is not the shadow of a doubt, after the year 1825, that electricity can produce magnetism ; but the reverse, Can magnetism produce electricity ? With ever-deepening interest as year after year goes by, the scientific world asks this question ; but, with all the most eminent men of Europe at work upon it, nature vouchsafes no reply, and so we come down to the last days of August, 1831, and to two men, one in the Old World, the other in the New, at work upon the problem, each unconscious of the other, an ocean between them. One of these men is Michael Faraday, Professor of Chemistry in the Royal Institution of Great Britain ; the other is Joseph Henry, Professor in the Albany Academy in the State of New York. These two were destined to find the key to the problem ; the answer to the question which had baffled the world of science for half a century.

"We say the last days of August, 1831, because at that date the work of the two men nearly touch in point of time ; but the actual discovery of magneto-electricity, the reader will see, if with kind patience he will follow our story, had been made by the one—that is, Henry—at least a year earlier, namely, in August, 1830, while it was not fully accomplished by the other until some thirteen months later, namely, the 24th of September, 1831 ; for this we shall find to be the date at which Faraday first fully recognised the phenomenon, and the principle by which it is controlled.

"To understand properly the work of these two men, in reference to the discovery of magneto-electricity, it is necessary to know something of the circumstances in which they were placed. When Sir Humphry Davy was asked which he considered his greatest discovery, he answered, 'Michael Faraday.' Entering the Royal Institution in an humble capacity in 1813, the flower of his genius growing and expanding under the fostering care of Sir Humphry, Faraday had attained a high position, and an enviable scientific reputation, in the great London institution. Director of the laboratory, he was surrounded by every possible facility for the prosecution of his investigations ; and what was, perhaps, even more important, had unlimited time at his command in London, the great centre of scientific light. He was now forty years of age. Henry was nine years younger. When Faraday first entered the Royal Institution as an assistant, Henry was but thirteen. Counting the years of his age with those of the century, he

Digitized by Google

had entered upon a course of original investigation as early as 1827; but amid such arduous duties as an instructor in the Albany Academy that, of all the twelve sisters of the year, he could only claim the month of August, the vacation time of the institution, as really his own. During four years he had been able to secure hardly more than as many months for regular scientific research. Could we look into his laboratory at this time, we would find, instead of the well-filled cabinets of the Royal Institution, only a few rude instruments, made at great expense of time and labour by his own hands. Even the material for these rude tools was often difficult to obtain. Experiments, for instance, sometimes stopped merely for the want of a scrap of zinc. We say 'could we look into his laboratory,' but we would seek in vain for a room which could properly be so called. Each series of experiments was necessarily carried on in the large hall of the Academy, which was available for Henry's use at no other time than during the summer vacation. Invariably all investigations came to a stop with the 1st of September, the beginning of the autumn session of the Academy, and were rarely resumed until the month of August came again. The invaluable stimulus of scientific intercourse and appreciation, too, was wanting. Very different was the dull commercial town of Albany from London, the intellectual metropolis of the world. A wide expanse of waters, not yet crossed by the swift ocean steamer, lay between Henry and all the culture of the Old World, and in provincial America little could be found to make good its place. Moreover, it must not be forgotten that Henry was the first who had undertaken a series of electrical experiments in America since the time of the immortal philosopher who first drew lightning from the clouds; 'the mantle of Franklin'—said Sir David Brewster—'has fallen upon his young shoulders.' Excepting Dr. Hare of Philadelphia, who was making notable improvements in galvanic apparatus, almost alone in the electric field, he stood to face the army of the Old World.

"Recalling the wide difference in condition surrounding the two, it is of no small interest now to see to what eminence each had at this time attained—the one during his eighteen years of culture and unimpeded work; the other in his few months of intermittent study, snatched at long intervals from the crowded days of four years of arduous professional labour. Constantly pursuing similar investigations, making many identical discoveries, Faraday and Henry seem like two competitors in a closely-contested race, upon whose course we have suddenly come in these August days of 1831, and with curious eyes we scan the field to see how they are running. Bence Jones says:

'If Faraday's life had ended at this time, when he finished his higher education, it might have well been called a noble success; but when we turn to the eight volumes of manuscripts of his *Experimental Researches* which he bequeathed to the Institution, we find that *his great work was just going to begin.*'

"Henry had begun his course with a series of original discoveries which might well weigh in the balance with anything Faraday had as yet accomplished, while in the particular field in which lay the '*great work*' of Faraday, which he was now '*just going to begin*' he had not only entered, but was already far ahead. The mysterious phenomena of the induction of electric currents, the reciprocal production of the magnetic and electric forces, were to him already old stories, intimately familiar, singularly well comprehended by him at this early date. He is in truth but amplifying the results which Faraday has just begun to seek, in these waning days of the summer of 1831. The younger man, as it were, had struck almost immediately into this particular path, and is now almost lost to sight in it, while the elder has only just come to the spot where his entering footsteps began.

"Let us dwell for a moment upon the importance of the answer to the great question we have been considering—the value to the world of the discovery made by these two men.

"It is not too much to say that it constitutes a veritable epoch in electrical science; upon it depend many of the most important applications of electricity to the uses of man, and new applications are developing day by day. Tyndall, the successor of Faraday in the Royal Institution, does not attempt to restrain his enthusiasm in the contemplation of it:

'I cannot help thinking,' he says, 'when I dwell upon it, that this discovery of magneto-electricity is the greatest experimental result ever obtained. It is the Mont Blanc of Faraday's own achievements. He always worked at great elevations, but higher than this he never attained.'

"Edward N. Dickerson, the eminent advocate, said of Henry:—

'The towering heights that were scaled by the daring spirit of Faraday from the East were at the same time surmounted from the West by our own countryman; both were climbing from opposite sides at the same time, and neither was conscious of the other's efforts till both stood face to face upon the summit.'

"But the standard of the West had been floating many months upon these towering heights before the standard of the East was planted. It was Henry's foot, not Faraday's, which first touched the untrodden peak.

"Let us see in what way Faraday and Henry, these two favoured children of nature, ask of her the all-important question so as to win at last a reply. Courtesy to the elder man and to the inhabitant of another country would seem to suggest that we first go over the sea to Faraday; but this may not be, for we must look among Henry's own instruments for the stepping-stone to the great discovery, made by Henry's own hands, to be a stepping-stone not only for himself but for Faraday.

"He had taken the soft iron horseshoe of Sturgeon, with its spiral of loose uninsulated wire, an infant lifting but a few pounds at an inordinate expense of battery power, and had transformed it into a giant capable of sustaining fifty times its own weight, under the stimulus of a battery of a single pair of plates of copper and zinc, scarce a hand's breadth in area. He had made two magnets—his 'intensity' magnet with a long single wire, and his 'quantity' magnet with many short wires; the latter the stronger in actual physical force, but the former endowed with the subtle capacity which enabled it to respond to the electric influence at long distances; the magnet, in fact, which made the electric telegraph a commercial possibility instead of a philosopher's plaything. He had discovered and made plain the law governing the relation between the electric flow and the electric resistances in battery and magnet; and had sent forth these children of his brain, through the pages of *Silliman's Journal*, to take their places as willing servitors in all the physical laboratories of the world. All this in the early days of this very year, in January, 1831.

"Of the theory of Ohm, now at the tongue's end of every schoolboy, but for a long time ridiculed or at least unnoticed by the scientific world, Henry in far distant America knew absolutely nothing. Five years later, in a letter written from Princeton, dated December 17, 1833, we find him asking Dr. Bache, 'Can you give me any information about the theory of Ohm? Where is it to be found?' In another letter of about the same period: 'Who is Ohm? What is his theory?' It was not until 1836, during his visit to London, that he sees at last Ohm's theory, and finds that, after all, it is in substance nothing more nor less than his own discovery, interpreted in the language of mathematical prophecy."

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES, F.R.S.

Some eight or ten years ago the art of electrical distribution was in such an embryonic stage that electrical engineers did not even know what was the most suitable current density for their mains. The alternate-current transformer was practically unknown, but people, recognising the advantages of high-pressure distribution, were employing their brains on what was called the "multiple series" system; accumulators also were thought of, but practically the low-pressure system was the only one at the disposal of electrical engineers. Nevertheless, in spite of the strides that electrical distribution from central stations had taken since those days, no new fundamental discoveries had been made, and he (Prof. Forbes) had nothing to alter in regard to the rules he had laid down in his

* Abstract of Cantor Lecture—II. 1, delivered before the Society of Arts, Monday, January 25, 1892.

Digitized by Google

previous Cantor lectures on the subject of electrical distribution. (*The Electrician*, October 9, 1885, *et seq.*, Vol. XV.)

Two problems which confronted the electrical engineer in 1885 confronted him still, viz., the proper size to give his mains, and how best to avoid variations of pressure at the terminals of the lamps. The current density should certainly not be greater than 500 amperes per square inch, and the variations should certainly be less than the total of 8 per cent. (+4 volts and −4 volts) at present allowed by the Board of Trade, and of which full advantage was taken by most supply companies.

So long as customers were scattered about in the manner they were at present the cost of copper must be out of all proportion. Electrical engineers should fairly face the fact that electricity must, as a rule, cost twice as much as gas, and to reduce its price they must set to work in the same scientific and determined spirit as did the early improvers of the dynamo. Several causes militated against the possibility of a cheap supply of electricity from a central station. The maximum demand was concentrated within a few hours, and largely exceeded the normal ; a central station plant was, therefore, but very partially employed, the engines worked uneconomically, fuel was wasted in heating up the boilers, &c. Indeed, at the date of his previous Cantor lectures these disadvantages figured so largely that it was a question whether the thing was commercially feasible. Many men thought it was not, and by their influence the system of granting licenses was originated to provide for cases where a few neighbours clubbed together and ran a small station of their own for private purposes. The work that had been done (of which we might well be proud), and the experience that had been gained since Major Marindin issued his memorable report on the numerous schemes for the electric lighting of the Metropolis, had caused a modification of views in this matter. Still, the fact remained that the average number of hours during which the lamps were in use was barely two hours per diem.

One result of this state of things was that clubs, restaurants, and the like, which required a steady supply of current, were somewhat unfairly charged, since they were in a manner mulcted for the short, sharp demands of other customers. If a steady demand were more general the selling price of the Board of Trade unit could be reduced to one-third of what it now was. An ordinary street arc lamp, for example, could be made a clear source of profit at £30 per annum, although, if the energy supplied were charged for at the rate of 7d. per Board of Trade unit, the annual rental would come out at £58—an instance of the difference in cost of a regular and an irregular demand. At the Athenæum Club a careful comparison had been made of the relative cost of private and public supply. The annual cost of the electric light at that club was £894 ; at 7d. per unit the annual bill would come out at £1,452.

Returning to the relative cost of electricity and gas, there was only one case in which the former was undoubtedly the cheaper, viz., in country houses. He knew of a house lighted with 210 16 c.p. lamps, and in which the lighting hours were long. The annual cost of electricity was £75, besides depreciation and the interest on an initial outlay of £1,800. Gas would have come to £300 a year.

Prof. Forbes then stated that he had circularised a large number of supply companies with a view to eliciting some information with regard to the relative masses of copper laid down as feeders and as distributing mains, &c., &c. He had, however, received but few replies—a result which was not surprising. At Kensington the mains weighed 133 tons, the feeders 15½ tons, and of the total capital of the Company 33 per cent. had been expended on mains, 43 per cent. on machinery and buildings, and 10 per cent. on secondary batteries. The Kensington and Knightsbridge Company had 12½ miles of mains. The Allgemeine Elektricitäts Gesellschaft, of Berlin, had 438 miles (700 kilometres) of main, which had absorbed no less then 1,500 tons of copper. No doubt to this lavish outlay on copper was due the excellence of this Company's supply. More money than had hitherto been usual might well be spent on copper. About one-half the total expenditure of a company might be in copper.

The three-wire system, its area of operations, practical and theoretical, and other details were next discussed. There were several methods of keeping the pressure at the lamp terminals constant ; the resistance of the feeders could be varied, a few accumulators, or a small auxiliary dynamo, might be employed to reinforce or reduce the volts, the station dynamos might be run at different voltages, and connected to appropriate feeders. The device of employing lamps of different voltage at different parts of the system was objectionable, and led to inextricable confusion. The auxiliary dynamo mode of feeder-pressure regulation was promising. Last summer he had carried out some encouraging experiments with a dynamo suitable for this purpose, namely, one built on his "non-polar" principle. It was coupled to a Parsons steam turbine running at 24,000 revolutions ; the armature was a solid bar of wrought iron 3in. in diameter ; the E.M.F. on open circuit was four volts, and on closed circuit two volts. Several large welds were effected with the current from this machine, and it ran continuously in a satisfactory manner.

The variation of 4 volts up and 4 volts down, at present allowed by the Board of Trade on a 100-volt circuit, was too much ; a variation of more than 2 per cent. was objectionable. To keep a check on the supply company serving his district, he had employed a recording voltmeter made by MM. Richard Frères, a type of instrument which should be used at the London County Council's testing stations. [Sample curves were then handed round.] At his own office in Great George-street the readings were always high during the busy hours, as it was close to the generating centre ; the variations were quite 8 per cent. At the Scottish Club in Dover-street the volts were low during the hours of maximum consumption.

After allusion to the several ways in which accumulators might be used in central-station practice, and the desirability of running the "pilot" wires to points midway between the feeding points, and not actually to them, the lecture concluded.

PHYSICAL SOCIETY.

At the meeting of this Society, on January 22nd, Prof. G. A. Fitzgerald, F.R.S., read a Paper,

"On the Driving of Electro-magnetic Vibrations by Electro-magnetic and Electrostatic Engines."

The author pointed out that as the electro-magnetic vibrations set up by Leyden jar or condenser discharges die out very rapidly it was very desirable to obtain some means whereby the vibrations could be maintained continuously. Comparing such vibrations with those of sound, he said the jar discharges were analagous to the transient sound produced by suddenly taking a cork out of a bottle. What was now required was to obtain a continuous electro-magnetic vibration analogous to the sound produced by blowing across the top of a bottle neck. In other words, some form of electric whistle or organ-pipe was required.

These considerations led him to try whether electro-magnetic vibrations could be maintained by using a discharging circuit, part of which was divided into two branches, and placing between these branches a secondary circuit tuned to respond to the primary discharge. This did not prove successful on account of there being nothing analogous to the eddies produced near an organ-pipe slit. The analogy could, he thought, be made more complete by utilising the magnetic force of the secondary to divert the primary current, first into one of the two branches and then into the other. If spark gaps be put between two adjacent ends of the branches and the main wire, then the magnetic effect of the secondary current should cause the spark to take the two possible paths alternately. Electrically driven tuning forks and vibrating spirals were cases in which magnetic forces set up vibrations ; but here the frequency depended on the properties of matter and not on electrical resonance. The frequency of delicate reeds could, however, be controlled by resonance cavities, with which they were connected, and he saw no reason why the same action could not be imitated electro-magnetically, using an electric spark as the reed.

Referring to the properties of iron in connection with electro-magnetic vibrations, he pointed out that a prism of steel one millimetre long had a period of longitudinal vibration of about one-millionth of a second, and as this was comparable with the rates of electro-magnetic vibrations the immense damping effect which iron had on such vibrations might be due to the setting up of sound vibrations in the material. Other methods of driving electro-magnetic vibrations had suggested themselves in the shape of series dynamos or alternators. The polarity of a series dynamo driving a magneto motor would, under certain circumstances, reverse periodically, and thus set up an oscillatory current in the circuit. Similar effects can be got from series dynamos charging cells or condensers. In an experiment made two weeks before, with Planté cells and a Gramme dynamo, reversals were secured every 15 seconds. Greater frequencies might be expected with condensers. The latter case he had worked out theoretically. He had also tried experiments with Leyden jars and a dynamo, but got no result. This might have been expected, for the calculated frequency was such as would prevent the currents and the magnetism penetrating more than skin-deep.

Calling the quantity of electricity on the condenser Q, the differential equation for a dynamo of inductance L and resistance r, and a condenser of capacity X, is $L\ddot{Q}+r\dot{Q}+Q/X=\dot{L}\dot{Q}$, or $L\ddot{Q}+(r-\dot{L})\dot{Q}+Q/X=0$. If $\dot{L}$ be $=0$ the solution of the equation is $Q=Q_0\epsilon^{-r/L\,t}\cos 2\pi t/T$, and the rate of degradation of amplitude depends on the factor $\epsilon^{-r/L\,t}$. If, however, $\dot{L}$ be greater than r the exponent of ϵ becomes +, and hence Q would go on increasing until limited by the saturation of the iron, or the increased resistance of the conductors due to heating.

Digitized by Google

A dynamo without iron, provided one could run fast enough to send a current through itself, would be likely to give the desired effect. The author thought that by making such a dynamo large enough and its armature very long, it would be possible to get a frequency of about one million.

Electrostatic machines seem, however, to be more promising driving agents. Like series dynamos their polarity depends on the initial charge, and can be easily reversed. Hitherto such machines have been inefficient mainly on account of the sparking in them, but Maxwell had shown how this could be obviated. There was the same kind of difference between electro-magnetic and electrostatic machines as between Hero's engine and the modern pr engine. Like modern engines electrostatic machines worked by varying capacity, but the effect of this variation in electrostatic machines was only to vary the frequency and not the rate of degradation. From the fact that electrostatic multipliers could be driven by alternating currents, he thought they might be made to drive alternating currents. If magnetic currents could be obtained then electrostatic engines would easily be produced.

In conclusion, the author described a modified electrostatic multiplier which he believed offered a feasible solution of the problem. In this machine the collectors were supposed joined to the ends of the vibrating circuit, and would, therefore, become + and − alternately. Inductors and brushes were to be so arranged that an insulating cylinder turning between them should have many + and − charges distributed alternately round its periphery. By suitable adjustment these charges could be collected at the proper instants, so as to keep up the vibration.

DISCUSSION.

The CHAIRMAN (Prof. Lodge) said the paper was very suggestive, and full of interesting points. The subject of electro-magnetic vibrations was attracting great attention in America in connection with the manufacture of light. Hertz oscillations die out too soon to be satisfactory, for their duration rarely exceeds a thousandth part of the interval between consecutive discharges. The theory of dynamos charging condensers he considered extremely interesting, and thought the fact that the damping factor could be changed in sign must have tremendous consequences.

Dr. W. E. SUMPNER asked a question about a method of doubling frequency of alternation, recently described by Mr. Trouton, in which the armature of one alternator excites the fields of a similar machine. Mr. Trouton had said that after once doubling the frequency it was not possible to go on doing so. He (Dr. Sumpner) thought that by adding other machines the frequency could be still further increased, and gave a proof of the fact.

In reply, Prof. FITZGERALD said that adding another machine increased the frequency by a given amount, and did not double the preceding one. Hence, to increase the frequency a thousand-fold a thousand machines would be required, and on this account Mr. Trouton considered it impracticable.

Prof. S. P. THOMPSON thought the Paper very suggestive, and the acoustic analogies very interesting. Melde's apparatus was an instance of doubling or halving a frequency. On reading the title of the Paper he he had expected hearing of a method of maintaining electro magnetic vibrations by giving occasional impulses in some such way as that in which a tuning-fork could be kept vibrating by allowing the hammer of a trembling bell to knock against it. There was another method of intensifying electric oscillations, which he had seen mentioned in a patent specification by Sir W. Siemens, who suggested using a series dynamo with a telegraph cable to augment the signalling currents. On the subject of ironless dynamos he (Prof. Thompson) desired further information. Some years ago he had made calculations, and found the speed at which they would require to run was so enormous as to be beyond the range of engineering possibility.

Mr. C. V. BOYS, referring to the author's suggestion of using an electric spark with alternate paths to maintain vibration, said that he had tried whether an oscillatory spark was displaced by a magnetic field; but the displacement, even when photographed by a revolving mirror, was barely appreciable.

Prof. PERRY asked for an explanation of the term "skin-deep magnetism." He was not previously aware that Sir W. Siemens had described a method of improving cable signalling by using a series dynamo. He himself had patented a somewhat similar arrangement. He had also made a dynamo without iron, but had not got it to work.

In reply to Prof. PERRY, the author of the Paper said that in electromagnetic vibrations the magnetic force alternates so rapidly that it could not penetrate far into the field magnet of a dynamo before it is reversed; hence the magnetism would only be skin deep.

Dr. BURTON suggested that a commutator with many segments, something like that used by Mr. Gordon in his researches on specific inductive capacity, might possibly be employed for producing high frequencies.

A communication on "Supplementary Colours," by Prof. S. P. Thompson, F.R.S., was postponed.

Water Power in India.—In connection with an extensive scheme for the irrigation of the Peryar district, it is proposed to utilise the power obtainable to generate electricity for lighting the city of Madras and other cities in the Presidency.

CITY OF MELBOURNE.

The City of Melbourne are advertising for tenders for (1) Electric Light Machinery, and (2) Electric Light Cables and Insulators. We give below the specifications issued. The conditions are the same for both tenders:—

SPECIFICATION AND CONDITIONS OF CONTRACT FOR SUPPLY OF ELECTRIC LIGHT MACHINERY.

The machinery to be supplied is that set out in the schedule hereto, together with such other articles as may be supplied in accordance with the provisions of this specification and conditions of contract.

Dynamos.—To be of approved make and design, to be continuous-current, suitable for running arc and incandescent lamps in series, capable of running from 50-60 1,200 c.p. lamps, speed not to exceed 1,000 revolutions per minute. To be both mechanically and electrically well constructed, having large surface for bearings and perfect lubrication. To be fitted with regulators to maintain a constant current.

Arc Lamps.—To be of latest design and make; to run without re-carboning for sixteen hours; to be nominal 1,200 c.p., each complete with globes of clear glass.

Hanging Boards.—One to be supplied for each arc lamp; to be fitted with switch for short circuiting lamp when necessary.

Hoods.—One hood of neat and serviceable design to be supplied for each arc lamp, to which attachment can be made for suspension of lamp.

Series Incandescent Lamps.—Series incandescent lamps to be of the following c.p.'s:—20-25-32, capable of taking the current used on the arc circuit, and guaranteed for 1,000 hours burning, and so constructed that in the event of the filament breaking the current will find an easy passage through the lamp.

Series Incandescent Socket and Shade.—To be of design suitable for out-door work, including inverted tin shade and glass globe to protect the lamp from moisture and mechanical injury.

Instruments.—Ammeters to be supplied for each dynamo, capable of reading up to double the normal current of the machine; to be of approved and reliable make.

Switch Boards.—To be of suitable make for arranging circuits as desired with plug connections; to be mounted on incombustible bases.

Lightning Arresters.—Lightning arresters of approved make to be supplied for dynamo circuits.

Tenderers are to supplement the schedule hereto with any articles not mentioned therein, but which form part of or are necessary for the satisfactory working of the system of lighting proposed to be supplied.

Materials and workmanship of the best quality only to be utilised in the carrying out of the contract.

The quantities set out in the schedule are as near as can now be estimated the quantities which will probably be required, but the contractor is to supply any greater or lesser quantity which may be required at the prices set against each item in the schedule.

CONDITIONS OF CONTRACT.

Time for Completion.—The whole of the plant to be delivered f.o.b. at port of shipment in first-class order, before the expiration of ——— weeks from the delivery of notice of acceptance of tender, as provided for in conditions of tender attached hereto.

Damages for Non-Completion.—Should delivery not be given within the time specified, the contractor shall pay to the Corporation for every week or part of a week thereafter, until such delivery shall be given, the sum of £25, as and by way of liquidated damages, and not in the way of penalty, and such monies for said damages may be deducted by the Corporation out of any monies due, or that may become due, to the contractor on account of this contract.

Inspecting and Testing of Plant.—The whole of the plant must be submitted to the Inspecting Officer of the Council at the premises of the contractor, to be tested by him in such manner as he may think necessary, and particularly as to insulation, efficiency, regulation and mechanical and electrical construction, and such plant must be certified to as satisfactory by such Inspector before delivery thereof will be accepted.

Should the contractor fail to construct any portion of the machinery in accordance with the foregoing specification, either as to material or workmanship, the Inspecting Officer of the Council may at any time prior to his giving his certificate of completion of this contract reject such portion of the machinery, notwithstanding that same has previously been passed by him.

Claims for Patents.—The contractor shall at his own cost supply all such machinery free from all charges or claims with regard to royalty on any patented article, and any claims that may be made in respect to the patent rights of any articles supplied by him in accordance with this specification which may be used in connection with his scheme in executing this contract.

Delivery.—The plant to be properly packed and delivered f.o.b. at port of shipment, inclusive of all charges up till such delivery, including insurance of the plant, but not including freight.

Payment.—Payment will be made by the Council to the contractor in manner following, viz., 75 per cent. of the amount of his contract upon receipt by the Council of bill of lading for such plant, and the balance of 25 per cent. 60 days after sight of bill of lading, such balance to be in the meantime subject to any claims which the Council may have against the contractor in respect of this contract.

Digitized by Google

Arbitration.—In the event of any dispute arising between the Council and the contractor in reference to any matter or thing connected with or arising out of this contract, such dispute shall be referred to and decided by arbitrators, one to be appointed by each party, and an umpire to be appointed by the arbitrators, and the award of such arbitrators, or any two of them, shall be final and binding upon both parties to this contract.

Interpretation Clause.—The word "Council" shall mean the Council of the city of Melbourne. "Contractor" shall mean the company, persons, or person who shall undertake the carrying out of this contract. "Inspecting officer" shall mean the person appointed by the Council for the purpose of inspecting and testing the plant contracted to be supplied. "Electrical engineer" shall mean the person for the time being holding the office of electrical engineer to the Council.

CONDITIONS OF TENDER.

Tenderers are required to submit with their tenders complete specifications and drawings of the whole of the plant which they undertake to supply, together with a complete description of their systems, and particularly showing the connections of series lamps and holders. Such specifications and drawings shall be deemed to be part of the specification of the contract. Tenderers are requested to state in their tender the time within which they undertake to give delivery, as provided in the conditions of contract. Tenders must be in the form annexed, and be signed by the tenderer with his full name and address. Within a period of three days after notice of acceptance of his tender shall have been given to him or his duly authorised agent, the successful tenderer must by himself or his agent execute a contract deed, having the specification, conditions of contract, and schedule of quantities and prices annexed thereto. Every tender must be addressed to the Right Worshipful the Mayor of Melbourne, Town Hall, Melbourne, endorsed on the outside with the name of the work to which it refers, and be enclosed in a sealed envelope. The Council shall not be bound to accept any tender.

TENDER.

TO THE RIGHT WORSHIPFUL THE MAYOR OF THE CITY OF MELBOURNE.

Under and subject to the conditions of tendering annexed hereto, ——— tender and offer to execute and perform the whole of the works and provisions, and supply all materials and labour, and everything of every kind respectively named, shown, described, and alluded to in the drawings, specifications, and conditions of contract and schedule of quantities and prices respectively, to be executed by and on the part of the contractor, for the supply of electric light machinery in conformity with the said drawings and specification, and under and subject to the conditions of contract, at the rates set out in the said schedule of quantities and prices. The total amount of this tender, calculated according to the said schedule of quantities and prices, is the sum of (£ ———). ——— hereby authorise ——— of ——— to act as ——— agent and to sign the contract hereon ——— on ——— behalf. Witness ——— hand ——— ———, this ——— day of ———, A.D. 18—.

——— Tenderer's name and address.

List of Quantities for Supply of Electric Light Machinery.

Probable quantities.	———	———
15	Dynamos, as per specifications ..... at	each
633	Arc lamps „ „ ..... „	„
500	32 c.p. series incan., as per specifictn. „	„
500	25 c.p. „ „ „ „	„
200	20 c.p. „ „ „ „	„
633	Hanging boards „ „ „	„
633	Hoods „ „ „	„
1,200	Series incandescent socket & shade, as per specification .... „	„
15	Ammeters, as per specification .. ... „	„
4	Switch boards „ „ ..... „	„
40	Lightning arresters, as per specifictn. „	„
3	Spare armatures ..... „	„
20	Sets of spare brushes ..... „	„
2	Sets of spare regulators for dynamos „	„

The whole of the articles above-mentioned to be delivered f.o.b., at ——— within the time mentioned in the foregoing conditions.

SPECIFICATION FOR SUPPLY OF ELECTRIC LIGHT CABLES AND INSULATORS.

The plant to be supplied is that set out in the schedule hereto :—

Cables.—To be of recognised good make; to be composed of seven strands of high conductivity copper wire, No. 18 S.W.G., tinned; to be insulated with vulcanised india-rubber, and braided with tarred hemp, the insulation resistance to be not less than 3,000 megohms per mile.

Insulators.—Alternative tenders are invited for the supply of insulators, viz.:

1st. To be of white porcelain of the screw bolt pattern, of a size suitable for the $\frac{7}{16}$ cable.

2nd. An oil insulator of a size suitable for the $\frac{7}{16}$ cable, of design to be submitted by tenderer.

Materials and workmanship of the best quality only to be utilised in the carrying out of the contract.

The quantities set out in the schedule are as near as can now be estimated the quantities which will probably be required, but the contractor is to supply any greater or lesser quantity which may be required at the prices set against each item in the schedule.

SCHEDULE OF QUANTITIES

For Supply of Electric Light Cables and Insulators.

Probable quantities.	———	———
160 miles	Insulated cable, as per specification, at	per mile
12,000	Screw bolt insulators „ „ „	each
12,000	Oil insulators „ „ „	„

The whole of the articles above-mentioned to be delivered f.o.b., at ———, within the time mentioned in the foregoing conditions.

LEGAL INTELLIGENCE.

The National Telephone Company v. John Milne and Sons.*

This action was again before the Sheriff, at Dundee, on Tuesday last, when

Mr. W. STILL, solicitor for the pursuer, said he had put the case on the roll in order that it might be remitted to the ordinary roll; but in the meantime he wished to state another answer to the defence of inadequate service. The pursuers sued for forehand rent or subscription. The defence related to the past year, with which they had done, and the defence was incompetent to any claim for rent or subscription for a period that had still to run. The only remedy which the defenders had seemed to be an action of damages. How did they know with regard to the period for which they were suing that the services to be rendered might not be perfect?

Mr. URQUHART objected to the case being on the ordinary roll. Though the case might be important to the Telephone Company, it was not more important to defenders than the sum of £8. 10s. There was no reason on their side why the case should be put on the ordinary roll.

Mr. STILL did not think the Company could have anticipated that any such defence was to be stated. It was a serious thing for the pursuers that in the defences of a small debt action such charges and averment should be made with reference to the Company's service.

Mr. URQUHART said it was the only defence they had. When the case was stated last Court day the Company had ample notice of the defences. There was no reason why this case should contain any question of importance. Its value was £8. 10s.

The SHERIFF: That is what it is to you; but it is not the value of the case to the Telephone Company. If all their customers were to do as defenders had done they might be ruined by the infirmities of the Small Debt Court.

Mr. URQUHART did not see why the Company should not be as subject to these infirmities as his clients. He, at all events, was willing to bide by the result of them.

The SHERIFF said the idea in sending the case to the ordinary roll was to get the matter settled as a question of principle, and to give each party the opportunity of an appeal to the Court of Session. His Lordship would let the case stand for a week so that the parties and himself might think about it. His Lordship was not, however, quite sure whether defenders had taken sufficient precautions to be able to bring a conclusive defence. It was not enough to have said that they tried to get a connection by telephone and failed. Defenders had probably only one witness to that effect for each occurrence; but in order to make a conclusive defence there ought to be two witnesses for each of the long series of connections that they tried to get, but got nothing back but profane language or some very unnecessary treatment. His Lordship did not know Mr. Urquhart would be really able to show, but he knew he did not mention any dates.

Mr. URQUHART: It would be a rather difficult thing to prove a series of specific dates. With reference to a remark by your Lordship that only one witness was available for each connection by telephone which Mr. Milne endeavoured to get, I may explain that the telephone was in the office, and what passes could be heard by the clerks sitting there; and I can prove that parties who tried to get a connection with defenders were unable to do so. If defenders had any guarantee whatever that the service was to be in any way satisfactory in the ensuing year they would be quite willing to pay the amount of this subscription.

Mr. STILL: It is a ridiculous proposition that this Company should give these subscribers a guarantee that they would have a satisfactory service for the current year. If the service proves throughout the current year not to be satisfactory, then they can have an action of damages against the Telephone Company for breach of contract.

Mr. URQUHART: The fact of the matter is that we are very anxious to have the services of the telephone in the office, and if the pursuers would agree to accept the £8. 10s. for the current year and not insist on any agreement, we will pay the amount of the current year's subscription.

After some discussion, the SHERIFF said the defenders would require to be able to tell with whom they had a connection, and the date, in order to show that the careless servants or negligent young ladies at the other extremity of the telephone either paid no attention, or, at all events, did not do their duty. Unless that were done, the Telephone Company could not tell who was the servant who did not do her duty. He thought both parties should try it for another year, and in the meantime be preparing their cases.

The case was then continued for a week.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 15, 1892.

Pending Patent Litigation.—Things electrical are rather quiet just now, the principal topics of interest being the outcome of several suits that are soon to come up before the Courts, and the various rumours flying about concerning the reorganisation of the Edison Company. Several important lawsuits are now on deck, chief among them being the Incandescent Lamp Suit, which will some time this month probably be heard in the Circuit Court of Appeals, unless some unexpected legal delay intervenes. As to what will be its fate there is no one ventures a prediction. Aside from this, two other important patents are soon to be put upon the rack, one of them being the Edison feeder and main patent, concerning which two suits are now pending. This involves the general principle of feeders in electric light service; and the legal questions involved are somewhat tangled. The other bit of litigation is with respect to the Edison three-wire system, the principal parties being the Edison Company and the Thomson-Houston Company. A large amount of testimony has recently been taken with respect to the operation of the Edison three-wire system in this city, and some of the facts brought out are interesting. One of them, as has long been an open secret, is the habit of grounding the third wire in service in this city and elsewhere, for the purpose of securing economy of copper and a better balancing of the system. It is naturally objected to by the fire underwriters, and ere long the question is bound to take a serious form.

Electric Railways.—There appears at present to be an unusual amount of interest in electric traction on the part of steam railway officials, and it would not be surprising at any time to learn that electric roads of much more imposing character than any that have yet been attempted were under way. The subject is an important one, of special interest in connection with the Chicago Exposition. It is already proposed by the Illinois Central Railroad that the suburban service should be carried on by electricity, especially as strong pressure is brought to bear on the railways by the public on account of the smoke nuisance, which is becoming almost intolerable in that city. A high-speed road between Chicago and Milwaukee is also being proposed, but nothing definite has as yet been done with respect to it.

The Forthcoming Meeting of the National Electric Light Association at Buffalo.—The coming meeting of the National Electric Light Association at Buffalo, N.Y., on February 23rd, is looked forward to with a good deal of interest, and from all that can be learned it is to be a working convention, with less of the junketing and more of real business than has usually been the case. One of the questions that will come up for discussion will be the desirability of holding annual conventions. The feeling has been growing of late that an annual convention would be productive of better results than the two now held, and it is not improbable that steps will be taken to make such an arrangement the future rule of action of the Association.

Electric Block Signalling.—Electric block signalling on railroads is one of the topics that is just now before the public. The recent accident on the New York Central Railroad has stirred up an unwonted amount of comment, and steps are now being taken by the officials towards equipping their line throughout with some form of automatic signal, which would be capable of preventing a repetition of the disaster of a few weeks since. At present the road is trying three systems, the Sykes, the Electro-Pneumatic system of the Union Switch and Signal Company, and the Hall Electric Signal. They have not yet taken decisive action as to which will be adopted for the part of the main line as yet unprotected, but are investigating all the systems mentioned, especially the last, with reference to its general adoption on the line throughout to Buffalo.

CORRESPONDENCE.

GRAPHICS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Your leading article on the development of practical geometry comes a little hardly upon those who have been endeavouring for years, in their humble way, to practise the very reforms which you have been so eloquently preaching.

Owing to the circumstance—the fortunate circumstance—that the Finsbury Technical College is not driven to prepare its students to pass any examinations prescribed by outside bodies, under curricula of a more or less antique character, the teaching of many subjects within its scope has developed in various directions. We may certainly claim that amongst these we make a moderate, though not an excessive, use of graphics, not only in the abstract domain of the solution of problems usually treated in the orthodox schools by analytical or algebraic methods, but in a host of more practical problems in mechanical and electrical engineering. Prof. Perry, to whose peculiar genius the mathematical course of the Technical College is indebted for many pieces of useful modernisation, has ever insisted on the value of graphic methods as affording ready means of arriving, not only at approximate solutions, but at clear understandings and mental appreciations of problems which might otherwise seem too transcendental to correspond to any actual facts. He has always advocated and practised a judicious use of graphic methods, not to the exclusion of analytical ones, but as helpful toward them, as explanatory of them, and as also of independent, because of pictorial, and, therefore, of mnemonic value. For my own part I think the latter point—to which your admirable article made no allusion—to be quite as valuable as the others. Consider the information conveyed (and when once conveyed never to be forgotten) by the shape of a curve of magnetisation, beginning at the origin, ascending slowly, then bending upward, rising almost perpendicularly, then turning over again and becoming almost horizontal. No table of figures, no algebraic formula, could ever be the instant reminder, which that curve is, of all the magnetic facts which it sums up in itself. It is so with the result of every graphic method; nay, it is so with the method itself; in carrying it out it prints itself upon the physical memory.

One great advantage to a student of the study of mechanical problems in the mechanical laboratory and electrical problems in the electrical laboratory during the same years as those in which he is studying problems in mathematics is that the former can be brought in to illustrate the latter, and make them more human and intelligible—more graspable, if I may put it so. By the study of valve gears it becomes almost an intuitive matter to see what is the proper expression for the sum of two simple harmonic functions of equal period, but differing in phase. After understanding such valve-gear problems it is a very simple matter to understand how in an alternate-current circuit the angle of lag of current must be such that its tangent is the ratio of inductance to impedance. This and the formula for the lagging current can be established simply, easily, without recourse to the solutions furnished in Boole's "Differential Equations," or to any recondite processes of integration unfamiliar except to those trained in the tricks of mathematical manipulation.

You speak of curve-tracing. Well, I have long held and urged that curve-plotting from formulæ ought to be taught at school before even quadratic equations are taught. It is a marvellous aid to algebraic work at all the stages between simple algebra and differential equations. Dr. Wormell, of the Central Foundation Schools, has long made this his practice. Would that all schoolmasters were as enlightened!

Two points, I submit, might well be urged as ripe for reform in the Schools and Universities of this country. First, the entire abolition of that hateful hybrid called Geometrical Conics; hateful because it is not geometrical, while it pretends to be; hateful because it goes about to establish, by long-winded proofs of schoolboy algebra, propositions which ought to be disposed of by a couple of lines of calculus. The

Digitized by Google

time that is wasted over these calculus-dodging round-about proofs would have been infinitely better spent upon learning the calculus. The main use of "geometrical conics" is to divert students' time from the calculus in order to spend it upon mastering long complicated proofs which the use of the calculus would have rendered superfluous. "Geometrical conics" belongs to that order of educational ideas of which the greased pole is the best symbol. It is a device to render climbing difficult, not to help the student to climb.

The second point for which the hour for progress is at hand is the introduction of projective geometry (real geometry, not schoolboy algebra under another name) as an alternative to that grave of blighted geometrical hopes—the six books of Euclid. Personally, I am glad that I was brought up on Euclid. Not that I learned geometry from the ancient Greek. Far otherwise. What geometry was in me at that date I had already learned by compasses and ruler. Working through Euclid nearly drove out of me all geometrical ideas. But to one who has already had the advantage of learning geometry Euclid forms an excellent introduction to the science . . . . . of logic.—Yours, &c., SILVANUS P. THOMPSON.

City and Guilds Technical College, Finsbury,
January 28, 1892.

STEAM-ENGINE ECONOMY.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In reply to Messrs. Parsons' letter in your last week's issue, we are sorry to think that the figures upon which Mr. Willans based his remarks and his diagrams in the discussion on Mr. Crompton's Paper should have been thought to be in any sense record figures. So far from this being the case, they were obtained from an engine which had not run very many hours. The rings had not, therefore, had time to come up to a face, and the engine was certainly not in a state to give the best possible results. It was a triple engine made for non-condensing work also, as all our engines have been up to now, and the best results could not be obtained from it, when working condensing; moreover, in plotting the diagrams illustrating Mr. Willans' remarks, an efficiency (E.H.P./I.H.P.) of 80 per cent. only was taken, as he stated at the time. This is less than we often reach with new engines, and is certainly less than is usually reached after a few weeks' work with direct-current dynamos working under the conditions which are present in electric lighting stations in this country.

At the low loads it was assumed that there were no reducing losses, which, even with the best dynamos, is not, strictly speaking, the case. The mean admission pressure in the cylinder at the highest observation taken in the condensing trial curve was 132lb. We have not a note of the pressure in the steam chest, but it would be probably some 5lb. or 6lb. higher. The figures were used for the purpose of illustrating Mr. Willans' straight line diagram, and in order to show (as was stated in his remarks) the gain which could be obtained, especially at light loads, even in the case of the very best possible non-condensing engine, by the use of a condenser. They were not intended in the case of the condensing trials to show by any means the best result obtainable. An engine which is to be used both condensing and non-condensing is at best a compromise.

The steam used in the trials was not tested at the time, but it probably contained 1 per cent. of moisture at the high loads, and was almost certainly dry, or even slightly superheated, at the lightest loads on account of throttling. The steam was taken through a separator in the ordinary way, but our trial boiler gives steam with about 2 per cent. of moisture in it, and this is not entirely removed by the separator so far as we have been able to ascertain.

Professor Ewing did not give in his report the source from which he obtained the figures quoted. The figure 18·6lb. has been several times almost exactly obtained by us; and we did not know, until he mentioned the matter to Mr. Willans, that he was quoting from the "Proceedings of the Institution of Civil Engineers." We should not have named that figure as an exceptionally good one, as we expect to do better.

In conclusion, we must heartily congratulate Messrs. Parsons on the results that they have obtained; we should not have written to the papers at all if these results had not been compared with our own.

Although we are quite sure that neither Messrs. Parsons nor Prof. Ewing had the least intention of saying anything which was not perfectly fair to us, there are many people who might make use of their report in a different manner, if we had not written as we did.

The method, we believe, adopted by Messrs. Parsons of varying the power of the engine by admitting steam intermittently is a most interesting one, and, so far as we know, it is the first time that it has been applied to a steam engine. Undoubtedly this method of reducing the power should tend in the direction of economy.—Yours, &c.,

WILLANS AND ROBINSON (LIMITED).

Picton House, Thames Ditton, Surrey, January 26, 1892. C. S. ESSEX, Secretary.

THE BOARD OF TRADE AND OVERHEAD WIRES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In view of your short note in your issue of to-day, I think it desirable to point out a little more particularly the meaning of the phrases "Rural Sanitary District" and "Urban Sanitary District."

Under the Public Health Act, 1875, and for the purposes of that Act, England, except the Metropolis, is divided into "Urban Sanitary" and "Rural Sanitary" Districts. By sub-section 6, Urban Districts consist of Boroughs, Improvement Act Districts not being within a Borough or Local Government District, and Local Government Districts not being within a Borough or Improvement Act District. The rest of England is, under this Act, divided into Rural Districts.

The names would seem to imply that an Urban District is a thickly-populated district, and that the Rural Districts consist principally of country lanes and fields. It is so far true that an Urban District always includes the towns and more populous places, but it also always includes a great stretch of country which is nothing but lanes and fields. That this is clear will be shown by the fact that the Borough of Ipswich, being the "Urban Sanitary District" of Ipswich, includes an area which is five and a-half miles long by four miles wide.

It follows from the above that the prohibition of overhead wires in "Urban Sanitary Districts," even though they are allowed in "Rural Sanitary Districts," would have a disastrous effect, and would, in fact, prohibit any use of overhead wires save in places where no one wants to place them.—Yours, &c.,

SYDNEY MORSE.

4, Fenchurch-avenue, London, E.C., January 22, 1892.

ELECTRO-MAGNETIC VIBRATIONS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have for some time been trying to devise arrangements by which electro magnetic vibrations might be maintained; and, following the example set by Prof. Fitzgerald at the Physical Society on Friday last, I wish to make one (the most workable) of the devices public, if you will allow me to do so in your columns, in the hope that some one who has command of the necessary apparatus may improve it, and carry out the experiments.

Imagine such a non-inductive bismuth wire spiral as is described in your issue of August 17, 1888, carrying a continuous current, to be placed in a permanent magnetic field, and to be surrounded by a solenoidal copper conductor which conveys the oscillatory current which is to be maintained. When the oscillatory current passes through the solenoid in one direction the magnetic field is increased in strength, the apparent resistance of the bismuth increases, and, consequently, the potential difference between its ends increases; and when the oscillatory current passes through the solenoid in the other direction the potential difference between the ends of the bismuth diminishes, because the magnetic field is reduced in strength. Either this increase and decrease of the potential difference between the ends of the bismuth wire or perhaps the changes in strength of the current in the bismuth wire or in some part of its circuit

Digitized by Google

may be applied, by electrostatic or electromagnetic induction, to give helping impulses to the oscillations at the proper times. It may be found necessary to delay the impulses by transmitting them through inductances so that they may only take effect at the proper times on the oscillations which are to be maintained. It may be that the changes in the bismuth take place so slowly as to be of use in maintaining only comparatively slow oscillations.

An arrangement of this kind obviously has certain advantages. There is no spark gap in which energy is frittered away in heat, and which may affect the working of the apparatus by variations in its resistance or by getting dirty. There is no rotating part the rate of rotation of which has to be kept constant. Neither the permanent magnetic field nor the continu ous current need be kept constant in strength.

Naturally I do not see the disadvantages so distinctly, but doubtless they will be discovered.—Yours, &c.,

January 25, 1892. T. A. GARRETT.

$d\,\mathrm{M}/d\,x$.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: The numerical values of $d\,\mathrm{M}/d\,x$, given on page 251, are derived from the formula on page 250, $\frac{d\,\mathrm{M}}{d\,x} = -\frac{6\pi^2\,\mathrm{A}^2\,a^2\,x}{(\mathrm{A}^2+x^2)^{\frac{5}{2}}}$ by substituting $\mathrm{A}=50$, $a=10$, and $x=0$, 10, 25, 50 successively. The only part which appears to present any difficulty is $(\mathrm{A}^2+x^2)^{\frac{5}{2}}$. To find this, "K. W. R." must first raise the quantity (A^2+x^2) to the fifth power, and then extract the square root of the resulting quantity. The calculation is, however, much simplified by the use of logarithms. The above formula only holds as long as a is small compared with A.—Yours, &c.,

Cavendish Laboratory, G. F. C. SEARLE.

Cambridge, January 26, 1892.

WHAT IS ELECTRICITY?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think you will scarcely endorse the opinion respecting this important question, stated in your issue of the 15th instant, to the effect that to attempt to answer it is to waste time.

Surely it is possible to formulate a plausible theory as to the nature of the electric "current," which shall be capable of direct experimental verification, and should this fail, the subject is certainly broad enough to admit of a second hypothesis, and, if required, of a third or fourth, which can be subjected to direct experimental test. There can be no question that a true understanding of the nature of the electric "current" lies at the root of all further advance in the production and application of energy in this form.

In your note respecting my previous letter you say I have "overlooked the fact that in the vast majority of cases the waste of energy in heating the wire is but a small part of the total energy conveyed by the current . . . . . we must . . . . . assume that the larger part of the energy is conveyed without any influence on the molecular structure of the wire."

Evidently this statement assumes the only evidence showing the electric transmission of energy to be a molecular function, to be that of the manifestation of heat. But is this so? As you remark, the waste of energy in heating is but a small part of the total energy "conveyed" by the "current." Then in what way is the larger part transmitted? If it be transmitted by ethereal wave motion, then the solid "conductor" is merely the receptacle for certain "waste" waves, which are made evident by a rise in the temperature of the wire. But take a case in which a conducting wire carries a high-tension current, but is not heated to any appreciable degree. Will it be maintained that this wire is in precisely the same state as a similar wire under normal conditions? If the energy is really transmitted by the surrounding ether, there being in this case no appreciable "waste" energy in the form of heat, it should make no appreciable difference if we substitute a glass rod for the copper wire; yet we know such a substitution would at once put an end to our "current." It seems to be very evident that, apart altogether from the heat effect, the transmission of energy by an electric current does in some way depend upon the molecular constitution of the solid conductor.

We have had all sorts of supposititious paths set forth as the lines in which the energy is supposed to travel. But no one volunteers any information as to *how* the energy is transmitted along these paths.

First we are told that the energy and current are both transmitted from the source to the work through the wire, the current being supposed to travel in one direction, the energy going in either direction, with or against the current.

Then we are told that the "current" goes by the wire, the energy traversing the surrounding medium; or both the current and energy traverse the medium, the current being to some extent under control of the wire, whilst "the energy paths," we are told, "are often very complex."

What does this mean? If the current and energy travel different paths, evidently we have two distinct phenomena to deal with. What chiefly concerns us is the transmission of energy; but if the energy travel by paths which are often very complex, what is this thing we call the "current," which is acknowledged to be more or less attached to the wire? What part is it supposed to play in the process of energy transfer?

But is it not quite as rational to assume that the state of strain, or rather the disturbance which is known to exist in the medium surrounding the wire, is an *effect* of an altered state of the wire, as it is to assume, *vice versâ*, that the disturbance in the medium is the *cause* of the altered state of the solid conductor. We do know that the solid conductor is absolutely essential to the transmission of *continuous* currents of low tension. But we have nothing to show that the presence of the ether is essential.

I have always understood that the ideal of the physicist was the reduction of all natural phenomena to the two prime factors—*matter* and *motion*. Yet the present tendency in certain quarters appears to be, not to seek the explanation of any new phenomenon by referring it to matter and motion, but to invent new properties to new ethers to suit the purpose in hand. We have already added to the list of natural phenomena one or more ethers, a presumptive *electricity* (according to some two electricities), and now we have to add one or more *energies*.

Energy used to be defined as "a capacity for doing work," but we cannot speak of the paths of a "capacity" as being very complex, or of a "capacity" travelling.

It will hardly be maintained that our knowledge of the ultimate constitution of matter is so complete as to warrant our assuming it to be impossible that matter can transmit energy in the manner to which we give the name "the electric current."—Yours, &c., WALLACE H. PAULL.

Belvedere House, Soho-road, Handsworth.

DOES ELECTRICITY EXIST?

TO THE EDITOR OF THE ELECTRICIAN.

SIR: It is eleven years since I introduced to the pages of *The Electrician* (Vol. V., p. 247) the question—"What is Electricity?" Discoveries since then have made the question still more interesting. You have raised it again in a leader headed, "Does Electricity Exist?" And I observe that, like a true scientist, you have allowed correspondents to give in your columns opinions adverse to your own. It is by such friendly intercourse that the truth may be found. I therefore hope you will allow me to lay before you some facts which go far to establish that electricity does exist. When referring to the measuring of a quantity of electricity you wrote, p. 214, "We can find no corresponding mode of measuring electricity unless as the charge in a condenser. But in this case we can easily recognise that the charge may be accounted for by a displacement strain of the ether; no idea of a concrete or material substance is needed." For the sake of explanation, let it be supposed that the condenser is a Leyden jar. Then I understand you to mean that when it is charged this is accomplished by the ether straining the glass,

In Franklin's day he and his American friends discovered that there were some kinds of glass jars which could not be made into Leyden jars—because the glass would not retain a

Digitized by Google

charge of electricity. Franklin supposed that this arose from the peculiar nature of the chemicals used in making that glass. I read the foregoing in Franklin's works in 1838, and proceeded to make experiments to discover the cause, and found that, although some kinds of glass were better than others for making Leyden jars, all kinds of glass jars, when received new from the glass works, will admit electricity to pass through them, so that they cannot retain a charge. I have had new-made glass jars which let the electricity pass through them as easily as water passes through a sieve, and yet when these same jars were kept for two three years then they made excellent Leyden jars, for they then retained electricity within them. Again, philosophical instrument makers who wish to give their customers faithful thermometers, act as follows:—They fill the tubes with mercury, seal the ends up, and allow them to lie past until the glass has become old, and then they engrave the indices. Had they done this when the thermometers were newly made the shrinkage of the glass through aging would have vitiated the indices.

With these facts before me, I cannot conceive it possible that the charging of a Leyden jar is a straining of the glass by the electricity, for the new-made glass before it has shrunk and hardened by time ought to yield to a strain more easily than the same glass when it is old and contracted by shrinkage. It is more reasonable to suppose that the atoms of electricity are of a definite size which can go through the large pores in the new-made glass, and that they cannot go through with the same freedom the smaller pores in the age-shrunken glass.—

Yours, &c.,

JAMES JOHNSTONE.

8, Merchiston Park, Edinburgh, January 25, 1892.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

This well-known handbook for the electrical and allied trades will be published on Monday, February 8th. Orders received before the day of publication will be supplied at the subscription price of 5s., post free 5s. 9d.; orders received after that date, 7s. 6d., post free in the United Kingdom, 8s. 3d. A very large number of copies are already on order, which will take some two or three days to execute. The 1892 issue is considerably enlarged, and several important new features have been introduced, including a mass of useful financial information regarding Electrical Companies, their Officials, Capital, Dividends, Market Quotations, &c. Every effort has been made to keep the book quite up to date, and it will be found that names of new firms, alterations of addresses, &c., have been brought up to within a few days of the date of publication.

TENDERS INVITED.—Tenders are invited for the supply of electric lighting plant for the City of Melbourne, Australia. Separate tenders are required (1) for electric lighting plant, and (2) for cables and insulators, in accordance with specifications, which may be obtained (or can be seen) at the office of this journal. Tenders will be received until April 2nd next. Some further particulars will be found in our advertising columns.

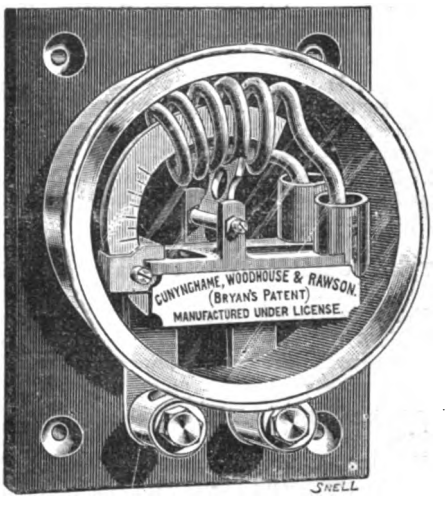
——— Our advertisement columns contain announcements that the Gas Committee of the Corporation of Manchester are prepared to receive separate tenders for the supply of dynamos for their central station in Dickinson-street, and for the supply and laying of electrical conductors and culverts therefrom. The general conditions of contract and specifications may be obtained on written application to Mr. C. Nickson, superintendent of the Gas Department, and tenders, addressed to the Chairman of the Gas Committee, must be delivered at the Gas Offices, Town Hall, not later than 10 a.m. on February 23rd.

APPOINTMENT VACANT.—The St. Pancras Vestry announce in our advertisement columns that they require an engine driver and fitter at the Regent's Park electric lighting station.

THE BRITISH ELECTRIC LIGHT COMPANY (LIMITED).—This Company, which many of our readers will remember so far back as 1878, is now reconstituted, with offices at Delahay-street, S.W. The Company undertakes all kinds of installation work for lighting or power, and has established works at Burlington-buildings, Heddon-street, London, W.

THE MARSON BATTERY.—Another primary battery is to be placed on the market. It is called the "Marson" battery, and it is claimed that the cell is specially suitable for domestic electric lighting. The negative element consists of a zinc calcium alloy immersed in dilute sulphuric acid, and the positive element of a mixture of compressed carbon, lead dioxide, &c., immersed in a solution the nature of which is not divulged beyond the fact that it consists of potassium, sodium, and bismuth salts. It is further claimed that, like the lithanode cell, if both elements are immersed in dilute sulphuric acid the cell is capable of being used as a secondary battery. As the most important part of this battery remains a secret, we have deemed it advisable not to tantalise our readers with all the details that have been communicated to us. The cell is made by the Marson Battery Company, of 29, Lloyd's-row, Clerkenwell.

IMPROVED CUNYNGHAME MAGNETIC CUT-OUT.—Messrs. Woodhouse and Rawson United are introducing a new form of magnetic cut-out in place of the well-known Cunynghame type hitherto so largely used on electric light installations in all parts of the world. The improvements consist in causing the current to pass round a pivoted solenoid, the two ends of which dip into mercury cups, this solenoid being drawn back on a fixed iron core when the current exceeds a predetermined strength. This strength may be altered by inserting more or less of the iron core into the solenoid.



This instrument has the advantage over the older type of requiring no insulation liable to combustion; it is mounted on slate or other incombustible material, no other insulation being necessary. A good feature of this instrument is the fact that the legs of the solenoid are always fully immersed in the mercury, irrespective of the current at which it is required to break circuit. The instrument is found to have a wider range than the old form, is more simple, and is said to be even more reliable.

J. D. F. ANDREWS' SYSTEM OF CONCENTRIC WIRING.—We have received a complete catalogue and price list from this firm, setting forth the virtues of the concentric system of wiring, and giving full tabular particulars as to the price of conductors, fuse-boxes, fuse-plugs, switches, wall sockets, special lampholders, tools, saddles, and other auxiliary apparatus. Messrs. Andrews' charges for wiring on their system range from 20s. to 40s per light. The absolute immunity of the concentric system from gradual short circuits is a great recommendation in many classes of installation work.

INTERNATIONAL OKONITE COMPANY (LIMITED).—The price-list of this Company is probably unique in its elaborate completeness; full particulars of every quality and class of electric conductor, from bell wire at £3. 15s. to concentric cable at £1,120 per mile, being included either in the yellow, green, salmon or pink lists. The system of colouring the pages of the different lists according to the class of conductor referred to thereon considerably facilitates the finding of the particular wire required. The lists are prefaced with some general remarks on the various manufactures of the Company, and contain the prices of wires and cables, special cables of high insulation, flexible cords and cable, and wires and cords, making in all about 60 quarto pages.

"THE MANUFACTURERS' ENGINEERING AND EXPORT JOURNAL."—We have received a copy of a new journal with the above title, which in appearance is something like a valued electrical contemporary. It contains an article on "Welding by Electricity" of much historic interest, and there are two fine still-life illustrations of the Phosphor-Bronze Company's Works, the photographs in both cases having apparently been taken during what may be called the "Influenza Era." If it were not that smoke can be observed in the dim distance, it might be conceived that the Phosphor-Bronze Company were retiring from any active concern in the trade of the country.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

December 28, 1891.

22,627. S. P. HOLLINGSWORTH. London. Improvements in electric locomotives or electric motor cars.

22,636. H. H. LAKE. London. Improvements in electrical conducting wires. (V. Hannetelle, France.)

22,640. W. B. SAYERS. London. Improvements in electric arc lamps.

December 29, 1891.

22,686. E. E. ANGELL. London. Improvements in electric forges.

22,687. E. E. ANGELL. London. Improvements in electric blank heaters for forging machines.

22,695. O. IMRAY. London. Improvements in apparatus for relieving electrical circuits from static charges of electricity. (The Westinghouse Electric and Manufacturing Company, United States.)

22,708. W. HELLESEN. London. Improvements in the manufacture of porous carbon for galvanic batteries and for filters.

22,718. G. D. BURTON and E. E. ANGELL. London. Improvements in machines for treating metals by electricity.

22,720. E. E. ANGELL. London. Improved methods of and apparatus for heating metal articles by electricity.

22,725. W. H. DINGLE and J. M. URQUHART. London. A new or improved method of making and breaking electric circuits and apparatus therefor.

December 30, 1891.

22,773. C. F. ENNIS. Clapham. Improvements in and relating to electric bells and indicators.

22,782. G. C. FRICKER. London. Improvements in electric arc lamps.

22,785. L. PYKE and E. S. HARRIS. London. Improvements in the field-magnets of dynamo-electric machines.

December 31, 1891.

22,817. J. H. RIDER. Halifax. Improvements in dynamo-electric machines.

22,820. E. F. FURTADO, A. ELLIOT, and CHEETHAM-STRODE (Limited). London. Improvements in connection with telephones.

22,837. H. H. BIGLAND and J. BURNS. Liverpool. Improvements in electric arc lamps.

22,852. F. TEAGUE. London. Improvements in and relating to electric meters.

22,854. E. PLACET and BONNET. London. Improvements relating to the electrolysis of metals. (Date applied for, under Patents Act, 1883, Sec. 103, July 17, 1891, being date of application in France.)

22,855. E. PLACET and J. BONNET. London. A method of extracting chromium by the aid of electrolytic baths with a base of salts of chromium. (Date applied for, under Patents Act, 1883, Sec. 103, July 17, 1891, being date of application in France.)

22,856. E. PLACET and J. BONNET. London. A method of extracting chromium by the aid of electrolytic baths with chromic acid base. (Date applied for, under Patents Act, 1883, Sec. 103, July 17, 1891, being date of application in France.)

22,858. E. L. MAYER. London. Improvements in, or connected with, electrical measuring and indicating apparatus.

22,871. J. J. ATWOOD. London. Improvements relating to the employment of electricity when carrying out certain surgical operations.

22,872. C. W. C. RIETTI. London. Rietti system of electric tubing.

January 4, 1892.

106. W. H. STURGE. Birmingham. Improvements in electric switches.

109. A. M. ROSEBRUGH. Toronto. Improvements in telephone exchange systems.

110. R. KENNEDY. Glasgow. Improvements in generating and distributing electrical energy.

111. R. KENNEDY. Glasgow. Improvements in distributing and converting alternating electric currents, and in apparatus therefor.

152. G. G. M. HARDINGHAM. London. Improvements in vulcanising the insulating covering of electric conductors. (J. J. C. Smith, United States.)

January 5, 1892.

177. G. E. PAINTER. London. Improvements in electric drop light.

207. E. J. HOUGHTON and W. WHITE. London. An electric regulator.

January 6, 1892.

253. W. T. GOOLDEN and S. EVERSHED. London. Improvements in magnetic apparatus.

259. A. B. WOAKES. London. A method of utilising electrical energy for the heating of water and other liquids.

278. W. WHITE and E. P. P. ALLAM. London. A wall contact and plug for electrical conductors.

310. J. D. F. ANDREWS. London. Improvements in or relating to joints and attachments for concentric armoured electric conductors and the methods of making the same.

January 7, 1892.

334. H. NEHMER. London. Improved form of a dry galvanic element.

355. E. C. FURBY. London. Improvements in or relating to the electro-deposition of tin upon metals.

359. SIEMENS BROS. and Co., J. NEBEL, and W. A. COLLINGS. London. An improvement in dynamo electric machines

360. SIEMENS BROS. and Co. (Limited). London. Appliance for equalising the loads of the several conductors of rotary phase-current installations. (Messrs. Siemens and Halske, Germany.)

372. N. BENARDOS. London. Improvements in soldering, melting, and coating metals by the aid of electriciiy.

Janauary 8, 1892.

406. The AMERICAN ELEVATOR COMPANY (Incorporated). London. Improvements connected with electric motors and electric elevator apparatus. (Otis Bros. and Co., United States.)

407. E. S. D'ODIARDI. London. Improvements in liquid electrodes.

408. E. S. D'ODIARDI. London. Improvements in electro-inhalers.

409. E. S. D'ODIARDI. London. Improvements in the electric static sprays.

410. E. S. D'ODIARDI. London. Improvements in pneumo dynamometers.

411. E. S. D'ODIARDI. London. Magneto voltaic electrode.

416. H. CAPELLE. London. An improved process for manufacturing galvanotypes. [Date applied for under Patents Act, 1883, Sec. 103, June 9, 1891, being date of application in France.]

January 9, 1892.

475. J. SWINBURNE. Teddington. Improvements in apparatus for testing insulation electric meters and alternating-current motors

486. R. E. B. CROMPTON. London. Improved variable resistances for electrical purposss.

SPECIFICATIONS PUBLISHED.

1890.

20,838. BIRKBECK. (Henrichsen.) Dry element for electrical purposes. (Price 6d.)

21,031. DAVIES. Secondary batteries, (Price 1s. 6d.)

1891.

1,046. GOULD and GOTTSCHALK. Prepaid telephonic messages. (Price 8d.

1,251. ATKINS (E. and W.) Electrical switches. (Price 8d.)

3,383. KINGDON. Dynamo-electric machines. (Price 8d.)

3,592. WHITEHEAD. Electric alarm apparatus. (Price 6d.)

4,554. REDFERN. (Lahmeyer and Co.) Armatures for electrical machinery. (Price 8d.)

4,579. BINSWANGER and SMEETON. Electric cigar lighters, &c. (Price 6d.)

14,796. ABEL. (La Compagnie AnonymeContinentale pour la Fabrication des Compteus à Gaz et autres Appareils.) Electric meters. (Price 8d.)

15,937. FELL (Weston). Electrical measuring instruments. (Price 6d.)

16,388. HAYS. Arc lamps. (Price 6d.)

19,900. THOMPSON. (Coffin.) Welding metals electrically. (Price 6d.)

19,901. THOMPSON. (Coffin.) Welding metals electrically. (Price 6d.)

20,257. THOMPSON. (La Compagnie de l'Industrie Electrique.) Electric lamps. (Price 6d.)

COMPANIES' MEETINGS & REPORTS.

The St. James's and Pall Mall Electric Light Company (Limited).

The ordinary meeting of the shareholders of this Company was held at St. James's Hall Restaurant, Piccadilly, on Tuesday last, Mr. Eustace J. A. Balfour presiding. The General Manager and Secretary (Mr. Frederic J. Walker) read the notice calling the meeting, and the report of the Directors and statement of accounts were taken as read.

The CHAIRMAN: The next business is to move that the report and accounts ended December 31, 1891, as submitted by the Directors, be received and adopted, and that the dividend recommended therein be declared payable on February 1st.

Mr. LATIMER CLARK seconded the motion.

The CHAIRMAN: I do not think it is very necessary for me to go in great detail into the working of the Company during the past year, because this report is very full, and I think on the whole gives as much information as it is desirable should be placed in the hands of the public The most important event perhaps of the year was the raising of £100,000 of additional capital in the form of Preference shares for the completion of

Digitized by Google

the northern station. The last £50,000 were largely over-subscribed and at a premium of 30s., a fact which, I think, shows that both the shareholders and the public in general show great confidence in the soundness of the business of the Company. This sum of £100,000 will, as you are aware, be chiefly devoted, and partly has been devoted, to the purchase of the site for and the erection of our northern station, and we expect this station, when erected, will probably be the best of its kind in the world, as it will contain all the cumulative experience that we have gained in the erection of our present station as well as all that of other companies gained in similar work. Machinery sufficient to furnish about 20,000 eight-candle lamps, is already nearly completed, and will be placed in position as soon as the building is ready to receive it. It may be of interest to the shareholders to know that a large part of this machinery was running and supplying light at the Naval Exhibition. It has been running up to this time without hitch or flaw, and we took it over not as new and experimental material, but as having been tried and found satisfactory. The great feature in the system which we are now developing is what we call the great trunk main, which is already partially made, and will connect the northern station with the existing station in Mason's-yard. It has a section of 8 square inches—probably the largest main ever made, and it is capable of carrying a current sufficient to supply 25,000 lamps. The importance of this cannot be over-estimated, because, well as our present station has worked up to the present time, and well as we expect it to work, it is impossible that it may not be necessary to carry out repairs in it which may involve its being shut down for a short time. When the main has been constructed, and when the Northern station is in working order, we shall be in a position in the slack months of the year to shut down one station or the other for any repairs that may be desirable, and to work entirely from the one that is not shut down. An eminent electrician, connected with electric lighting, told me some months ago that all new electric light stations should be supplied with two chimney shafts. Whether he is right or not in his opinion I do not venture to say, but the system that we propose to adopt combines all the advantages of his proposal, and a considerable number of other advantages besides, in addition to being much more economical. I do not think I need say any more on the particular subject of the working of the Company during the past year; but I should like before I sit down to touch on a matter which I regard as of very great importance, not only to this Company, but to all electric lighting companies, and to the whole question of the electric lighting of the metropolis—I refer to the legislation under which we have obtained our Provisional Order. When, first of all, legislation was started in respect of electric lighting, the term fixed for the expiration of a licence was seven years—that is to say, that the licence could be terminated by the local authority or by the Board of Trade after seven years. This legislation seems to have been based under a sort of morbid terror that electric lighting companies were going to become enormous corporations, with great powers of monopoly. The Provisional Order under the same Act was limited to 21 years. The result of this extraordinary Act was that everybody who had invested their money in electric lighting concerns lost it, and that the public was kept out of the electric light for several years, London being left far behind other European cities and many towns and villages in America. Under the present Act, each Provisional Order lasts for 42 years, but all Provisional Orders are subject to two conditions—first, that the Board of Trade can revise rates at the end of seven years; that is to say, the Board of Trade can step in and say, "You are charging too much:" and second, that that body has arranged to put into every parish, district, or area in London at least two electric light companies. Now, if you will consider these points for a moment I think you will see that they act first of all against the consumer and directly also against the electric lighting companies. As we have only a terminable lease of life—42 years—it is absolutely necessary for us to put by what we have termed a redemption fund, calculated to be sufficient to replace the deficit in the capital account which we anticipate at the end of 42 years, when we shall be or may be obliged to hand over our business at a valuation by the local authority who has the option of purchasing. If our tenure were permanent, after paying to our shareholders a reasonable dividend, we should use the amount of this redemption fund in reducing the cost of the light, and in the present year we made a rough calculation even if we paid to our present shareholders the same dividend we propose to pay, I think we should have been able to reduce the cost of the light to the consumers about 1d. out of every 7d. Secondly, the power of septennial revision introduced an element of uncertainty to the business which must be injurious to all interests concerned. Nor is it likely that this revision can be made to work in a practical manner. Had the Board of Trade seen fit to grant complete monopolies in every district—that is to say, one company in each district—subject to some scheme of revision on a previously defined scale, such a system might have been found to be satisfactory; but as it is, on what basis are they going to revise? Supposing we have in one district, or any parish in London, the case of two companies, one of which has paid on an average for seven years a dividend of 20 per cent, and the other has paid during the same period a dividend of 2 per cent., is the Board of Trade going to insist upon the reduction of the cost of electric lighting because one company is paying and the other is not? In that case you would find the shareholders in one company absolutely ruined; in fact, they cannot get out of this, they must be either fair or unfair to one of the companies, or unfair to the consumer's district. In fact, I may say that the two systems which they have adopted of what they term limited competition and a system of revision of rates are absolutely inconsistent. Now, lastly, the system of limited competition is injurious alike to consumer and producer in that it makes it necessary to earn a dividend on a much larger capital than would be necessary to supply that district. Supposing you have two electric light stations, and two sets of mains in one district instead of one, the dividends have to be earned on a capital, which I think, I am not overstating in saying is at least twice what it ought to be. You have, in addition to that, the disadvantage that the streets are twice cut up, and we have also to consider that the initial expenses of the Company have to be twice gone over; and these are items which are very much larger than those who are not in the business are apt to think. I do not think I have anything more to say, but I shall be glad to answer any questions that may be put to me.

Colonel FRANCIS said he wished to put a few questions. Referring to paragraph 7 in the report, in which the net earnings of the Company during the past year were stated to be £10,395, he maintained that the net earnings had been £15,409, and that part of the law charges—£558—included some of the expenses incurred in 1890, and therefore ought not to come out of revenue in 1891. He had added to the net earnings, as stated in paragraph 7, the total amount of the depreciation fund and the redemption fund. His reason was as follows:—He found that a very large sum—£1,702—had been charged during the year to the repair of machinery. When a Director of the Company he consulted the makers of their machinery and they informed him that if the machinery were kept in perfect repair the depreciation was very slight. He did not say that there was no depreciation; but he said that the sum of 5 per cent. on the outlay for the machinery would be ample for the purpose. At any rate, he asked on what calculation the enormous sum of £4,013 had been arrived at after £1,702 had been spent. Seeing that the last meeting he attended was a painful one, he wished to know the grounds on which the Directors said that there would be a loss of capital on the expiration of the term covered by the Provisional Order. Turning to capital account, he found that the sum of £20,297 was paid for the new site. They must remember that Mason's yard cost £9,500, and that a site within 50 yards of the present new site was open to purchase by the Company whilst he was a Director, for £1,100 and £100 a year. He had had the site valued by the most experienced surveyor of the parish, who placed its value at £8,000. The offices of the St. James's Company were small in size, and, as far as he had observed them, plain in appearance. There were three small rooms on which the Directors had managed to spend £700 in furniture. The machinery and plant stood at £12,000, and he wished to ask whether that machinery was at the new station, or had it been supplied to the original one? Could not the capital account of the two stations be kept separate so that they might know exactly what each one cost? What sum was to be paid for building the new station? £100,000 had been obtained from shareholders for preference shares, bearing interest at the rate of 7 per cent. At the time that this was proposed there was a strong opposition, for it was perfectly well known that the money could be raised at 5 per cent. In fact, an offer of £50,000 had been made to the Directors, and spoken of at the last meeting. It was urged that if the sum was large, at any rate the original shareholders would benefit by the transaction. The original holders did benefit by the transaction, which was made in their interest. He thought it was absolutely necessary that the shareholders should obtain information as to what was going on more than once a year. £350 was spent on printing and advertising, but he had never seen an advertisement in connection with the Company; and he had received no information of what was going on since last meeting. The questions he would like to ask were: On what scale had the Directors gone in forming an estimate of the depreciation of the machinery? Had the whole of the sum of £558 become due for law charges in 1891? On what grounds did the Directors represent that there would be loss of capital on the expiration of the term covered by the general order? What course did the Directors intend to pursue in relation to their fees? Did they intend to replace "not to exceed £1,500" in the paragraph in the Articles of Association bearing on this matter? As the printing was charged at the rate of £350 a year, would the Directors see that a full report of this and succeeding meetings be sent to each shareholder? Would the Directors further arrange that the meetings should be held in January and July? What was the cost of the new site, and who was the vendor who held the property? What surveyor, acting on behalf of the Company, recommended that price to be paid, and what sum was to be paid under the contract for building the new station?

Mr. H. J. MUIRHEAD thought that had they held their meeting in the City they would not probably have been deprived of the presence of two of their Directors. He did not think that the accounts were an exhibition of economy in the management of their affairs. To begin with, not only did they put down £1,700 for maintenance and renewals, but there was an enormous amount of £4,000 for depreciation, so that at least £7,000 was put against depreciation. He presumed that this Company was governed by section 2 of the Electric Act, 1882, and in that case it was provided that if the Company were taken over by the Local Authority the price paid would be the fair market value at the time of purchase. He observed that £1,000 accumulative a year at compound interest came to 75 per cent.; consequently, they ought to have £75,000 at the rate of 3 per cent., and £95,000 at 4 per cent. He thought that the Chairman must agree that the sum would be totally beyond the requirements of the case. He thought that £558 was an enormous sum for legal expenses, especially as he understood they were in connection with an arbitration case which the Company had won, and the other side would have had to pay. The Chairman had stated the case fairly respecting the Board of Trade, against which body there was no use knocking their heads.

The CHAIRMAN, in reply, said that the scale on which they had based their estimate of depreciation was the ordinary one used in businesses of the kind. On the face of the accounts it was not the case that the whole of the £558 had become due for law charges in 1891. It was a perfectly notorious fact that there would be a loss of capital at the expiration of the term of the general order. The Directors had discussed the matter, and that was their view. As to the course the Directors were to pursue in respect of their fees, an answer to the question had been given to Mr. Muirhead in 1891 in special meeting. The Directors had no such intention as to replace the words "not to exceed £1,500" in

Digitized by Google

the Articles. Their printing was at the rate of £350 a year. The Directors hesitated to send a report of their proceedings to shareholders, having regard to the expense. They would consider it, as well as the question of having half-yearly meetings. The surveyor of the Company was Mr. Wilkinson, and the price paid for the site was £20,000. The contract for building the new station was £19,000, He could not say at that moment what amount had been spent on plant and machinery. It was much too early to say whether the accounts of the two stations could be kept separately. The accounts were kept under Board of Trade rules. The only reason why they had met there was that they were within their own boundaries, and they were patronising a good customer.

The resolution was then carried.

The CHAIRMAN then moved the re-election of Mr. Egerton H. Clarke and Mr. H. Woodburn Kirby to their seats at the Board.

Mr. HOMAN asked that the names might be put separately.

The CHAIRMAN thereupon moved the re-election of Mr. Clarke.

The motion having been seconded by Mr. Darnton Hutton,

Mr. HOMAN moved as an amendment that he be not re-elected, principally on the ground that Mr. Clarke had sold on the Stock Exchange a founders' share for £350, and, having done so, went to the meeting of the Board at which the dividend was to be decided.

Mr. H. J. MUIRHEAD seconded the amendment. There were certain things in connection with the Company which could not bear the light of day, and they ought to get Mr. Clarke's explanation of his conduct.

The CHAIRMAN said he was extremely sorry that Mr. Clarke was not present, and that such an unpleasant incident had arisen. But Mr. Clarke, when he went to the meeting referred to, did not know what their decision would be.

The amendment, on being put, was declared carried.

The CHAIRMAN then announced that the Board demanded a poll, and appointed that day week, from three to four p.m., on which to take it.

Mr. Homan and the Auditor were appointed scrutineers.

On the motion of the CHAIRMAN, seconded by a SHAREHOLDER, Mr. Kirby was then re-elected to his seat at the Board.

The auditors, Messrs. Deloittes, Dever, Griffiths, and Co. were reappointed, on the motion of a SHAREHOLDER, seconded by Mr. MUIRHEAD; and a vote of thanks having been accorded to the Chairman for presiding, for which he briefly expressed his acknowledgments, the proceedings were brought to a close by passing a vote of thanks to the General Manager and Secretary, the chief engineer, and the staff.

J. E. H. Gordon and Co. (Limited).

The second annual general meeting of this Company was held on Monday last, at the offices of the Company, at 11, Pall-mall; Mr. J. E. H. Gordon, M.Inst.C.E., Chairman of the Company, presiding.

We have received from the Company the following particulars:—

The SECRETARY (Mr. Henry Sinclair) read the notices convening the meeting, and the minutes of the previous meeting were confirmed.

The report of the Directors and statement of accounts were taken as read, and the CHAIRMAN explained that the year had been one of increasing and satisfactory business; the turnover for the second six months of 1891 having been more than double that of the first six months. He further stated that among the numerous important works that have been carried out during the year were the electric lighting of Carlow (described in *The Electrician*, July 24, 1891) and Larne in Ireland, and the erection of the large central station for the Crystal Palace District Electric Supply Company, which is now supplying the greater portion of the electricity in use at the Electrical Exhibition at the Crystal Palace. He was able also to announce that arrangements have been made for adding to the electric lighting department, a department to deal with the important problem of electric traction.

A dividend of 30 per cent. for the year was declared, and Mr. W. J. RIVINGTON (Managing Director) proposed the adoption of the report and accounts, which was seconded by Mr. S. W. SEARLE, and agreed to unanimously without discussion.

The proceedings then terminated.

In reference to the meeting of Messrs. J. E. H. Gordon and Co. (Limited), given above, it may be of interest to give the last statutory return of the Company lodged at Somerset House:—

J. E. H. GORDON AND CO. (LIMITED).—The statutory return of the above-named Company, made up to January 31, 1891, was filed on October 28, 1891. The Company was registered on September 19, 1890, with a nominal capital of £50,000, in £10 shares, to acquire and take over as a going concern the business of J. E. H. Gordon, electrical engineer, and to carry on the business of electrical engineers, and the business of constructing, manufacturing, supplying, and maintaining electric light machinery and apparatus. An agreement, made September 15, 1890, between J. E. H. Gordon and W. J. Rivington of the one part, and H. Sinclair of the other part, fixes the purchase price of the above-named business at £30,000, to be fully satisfied by the allotment of 2,000 £10 shares to J. E. H. Gordon or his nominees, and the allotment of 1,000 £10 shares to W. J. Rivington or his nominees, provided that the said W. J. Rivington applied for and accepted 200 £10 shares, and paid the full amount for such shares immediatly upon the incorporation of the Company. At the date of making up, 3,205 shares had been taken up, of which 3,000 had been issued as fully paid. Upon the remaining 205 the full amount had been called, resulting in the payment of £2,000, leaving £50 in arrears. The principal subscribers are James E. H. Gordon, of 1, Queen's Gate-gardens, S.W. (2,000), and W. J. Rivington, of 21, Gledhow-gardens, South Kensington, S.W. (1,200), the remaining five shareholders taking one share each. Registered office: 11, Pall-mall, London, S.W.

City and South London Railway Company (Limited),

The following is the report of the Directors, to be submitted to the half-yearly ordinary general meeting, to be held at Winchester House, Old Broad-street, London, E.C., on Tuesday next, February 2nd, at 12 noon:—

The receipts during the half-year from all sources amounted to £20,243. 15s. 4d., and the cost of working for that period to £15,516. 9s. 8d., leaving a net profit of £4,727. 5s. 8d. Including the amount brought forward from last half-year, the net revenue account shows a balance of £5,326. 0s. 9d.; of this amount the Debenture interest absorbs £4,304. 10s. 0d., leaving a balance available for dividend of £1,021. 10s. 9d., out of which it is recommended that the full dividend of 5 per cent. be paid on the Perpetual Preference shares; and although the balance remaining would allow of a very small dividend on the Ordinary shares, it is recommended that it be carried forward to the next account.

The number of passengers carried by the railway in the past half-year was 2,749,058, showing an increase over the previous six months of 336,712, making the aggregate number carried since the opening of the line 5,349,580.

Your Directors have, after mature consideration, found it necessary to vary the fares at certain stations between stated hours, with a result advantageous to the Company and to the comfort of the travelling public. To meet the convenience of residents along the line, a system of season tickets has been in operation since the 1st November last.

Notwithstanding a considerable increase in the rates and taxes and other items over which your Directors have no control, they have satisfaction in reporting that the total expenditure shows a small decrease over that of the previous half-year, and it is hoped that some further reductions may still be made.

The rolling stock has recently been increased by the addition of the two new locomotives referred to in the last report, which it is hoped will give greater power and speed in working the trains, and the six additional carriages have also been delivered. The fourth engine and dynamo are now in course of erection for the generating station.

During the past three months the traffic of the railway has shown a marked and satisfactory increase, which there is every reason to hope will continue and be still further augmented. To meet this growing traffic arrangements are in progress for providing a more frequent train service during the busiest hours of the day. After the experience of the past year there is every reason to be satisfied with the use of electricity as a motive power for the working of this railway, and for a confident belief that when all the details are fully perfected it will be found to be at once safe, convenient, and economical.

The difficulties which have been experienced in dealing with the increasing traffic at the King William-street Station, owing to its confined dimensions and the steep incline leading to it, have induced your Directors to deposit a Bill by which they seek Parliamentary powers to make a foot subway connecting the terminus of the London, Brighton, and South Coast Railway Company at London Bridge with the station already authorised to be constructed at the corner of Denman-street, and also to construct two additional tunnels under the river with easy inclines to a central station at the corner of Lombard-street, and thence under Moorgate-street to the Angel at Islington, where ample siding room can be obtained at a small cost. These proposals meet with the approval of the Directors of the London, Brighton, and South Coast Railway, and will bring upon the line a very large and profitable traffic, and at the same time reduce considerably the cost of working the existing railway. It is also proposed to construct an inclined footway connection between this Company's station and the Monument Station of the Metropolitan and the Metropolitan District Railways, and powers for that purpose are included in the Bill. The Bill will be submitted for your approval at the conclusion of the half-yearly meeting.

Owing to other engagements, Mr. Alexander Hubbard has resigned his seat at the Board, and the vacancy thus caused has been filled by the election of Mr. Edwin Tate, of 21, Mincing-lane, London. The Director retiring is Mr. Charles Grey Mott, who is eligible for re-election. The auditors retire and are also eligible for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

JACQUARD AUTOMATIC READING AND PUNCHING MACHINE SYNDICATE (LIMITED).—This Company was registered on January 21, 1892, with a capital of £150,000 in £1 shares, by Hays, Schmettau and Co., 31, Abchurch-lane, London, E.C. The objects are (*inter alia*) to carry on the business of an electric light company in all its branches; to construct, lay down, establish, fix, and carry out all necessary cables, wires, lines, accumulators, lamps, and works; to generate, accumulate, distribute, and supply electricity; and to carry on the business of electricians, electrical contractors, electrical and mechanical engineers, and suppliers of electricity for the purposes of light, heat, sound, power, or otherwise; and of manufacturers of and dealers in all apparatus required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. Solicitors: Arthur T. Ashwell, Nottingham; and Hays, Schmettau, and Co., of 31, Abchurch-lane, E.C.

JOHN LONGBOTTOM AND CO. (LIMITED).—This Company was registered on January 15, 1892, with a capital of £2,000, in £10 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to carry on the business of machine and engineers' tool makers, makers of power looms and other machinery, millwrights, mechanical and electrical engineers, iron and brass founders, workers out of mechanical inventions, &c.

Digitized by Google

MAYBURY AND MARSTON (LIMITED).—This Company was registered on January 25, 1892, with a capital of £50,000, in £5 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to acquire and carry on the business of iron and steel manufacturers, mechanical and electrical engineers, tool makers, iron and brass founders, &c., carried on by Edward Maybury and Edward Marston at the Perseverance Iron and Steel Works, Brindle Heath, Pendleton, near Manchester, and at Huyton Quay, near Liverpool, under the style or firm of "Maybury and Marston." Registered office: The Perseverance Iron Works, Pendleton, near Manchester.

READING ELECTRIC SUPPLY COMPANY (LIMITED).—This Company was registered on January 22, 1892, with a capital of £75,000, in £5 shares, by Henry F. Kite, 11, Queen Victoria-street, E.C. The objects are to acquire and take over as a going concern the buisness now carried on by the Laing, Wharton and Down Construction Syndicate (Limited), at Reading, in the county of Berkshire, under the style of "The Reading Electric Light Depôt," to carry on the business of an electric supply company in all its branches; and in particular to construct, lay down, establish, fix and carry out all necessary cables, wires, primary, secondary, and other batteries, accumulators, lamps, apparatus and works; to generate, accumulate, distribute, and supply electricity and electrical energy; and to carry on the business of electricians, electrical and mechanical engineers, suppliers of electricity and electrical energy for the purposes of light, heat, sound, motive-power or otherwise, and to manufacture, buy, sell, hire, use, let and deal in dynamos, lamps, wires, cables, wires, insulating materials; accumulators, primary, secondary, and other batteries, telephones, and other apparatuses. The subscribers are:—

Registered without Articles of Association.

CAMBERWELL AND ISLINGTON ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The first annual return of the above-named Company, made up to January 4, 1892, was filed on January 18, 1892. The Company was registered on June 28, 1890, with a nominal capital of £1,000, divided into 900 ordinary and 100 founders' shares of £1 each. At the time of making up, 7 founders' shares had been taken up, the full amount being considered as paid upon each. The original signatories are the only shareholders, and no agreements for the taking over of any businesses, contracts, plant, &c., have as yet been filed. Registered office: Westminster Chambers, 5, Victoria-street, Westminster, S.W.

DEVONSHIRE ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The first annual return of the above-named Company, made up to January 4, 1892, was filed on January 18, 1892. The nominal capital is £1,000, divided into 900 ordinary and 100 founders' shares of £1 each. Seven founders' shares only have been taken up, the full amount being considered as paid upon each. Registered office: Westminster Chambers, 5, Victoria-street, Westminster, London, S.W.

EAST COAST ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The first annual return of the above-named Company, made up to January 4, 1892, was filed on January 18 following. The nominal capital is £1,000, divided into 900 ordinary and 100 founders' shares of £1 each. Seven founders' shares only have been taken up, all of which were issued as fully paid. Registered office: Westminster Chambers, 5, Victoria-street, Westminster, S.W.

ELMORE'S PATENT COPPER-DEPOSITING COMPANY (LIMITED).—The annual return of the above-named Company, made up to the 13th January, 1892, was filed on the 21st January following. The Company was registered on the 18th January, 1889, with a capital of '£200,000, in £2 shares, to purchase, take over and work the whole of the British patents of Messrs. F. E. and A. S. Elmore, and numbered 10,720 of 1884; 1,737 of 1885; 4,499 of 1885; 8,707 of 1885; 10,451 of 1885; 11,800 of 1885; 9,214 of 1886. Together with the following Provisional Specifications of British Patents, being numbers 11,778 of 1888; 12,022 of 1888; 12,264 of 1888; and complete specification 16,637 of 1887; and all improvements relating to the treatment and electrical deposition of copper and other metal articles, and to carry on the business of an electric light company in all its branches, including that of electricians, electrical contractors, mechanical and electrical engineers and suppliers of electricity. At the time of making up, 77,295 out of the 100,000 shares had been taken up, and upon all of these the full amount (£2) had been called, resulting in the payment of £107,990. The total amount agreed to be considered as paid on 23,300 shares was £46.600, and £7 10s. has been paid on 15 shares forfeited. Registered office: 64, Cannon-street, London, E.C.

ELMORE'S WIRE MANUFACTURING COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 13, 1892, was filed on January 22nd following. The company was registered on March 15, 1890, with a capital of £300,020, divided into 150,000 ordinary and 10 founders' shares of £2 each, to acquire from Elmore's Patent Copper Depositing Company (Limited) certain patent rights, licences, and privileges, and to carry on the business of an electric light company, including that of electricians, mechanical and electrical engineers, electrical contractors, suppliers of electricity, and manufacturers of and dealers in electrical apparatus and appliances. At the time of making-up, 66,025 ordinary and all the founders' shares had been taken up, upon all of which the full amount had been called, resulting in the payment of £119,318. 15s., and leaving £12,751. 5s. in arrears; £390 has been paid on 1,360 shares forfeited. Registered office: 64, Cannon-street, London, E.C.

FOWLER, LANCASTER AND CO. (LIMITED).—Resolutions passed at an extraordinary general meeting of the shareholders of the above Company, held on November 11, 1891, and confirmed November 30, 1891 (the notice of which was filed on December 29, 1891), as follows:—"(1) That the borrowing powers of the Directors, under Clause 8 of the Articles, be increased by striking out the figures '£3,000' and inserting in their place the figures '£5,000 in addition to debentures.'" "(2) That the time required for giving notices for meetings be reduced by striking out the word 'fourteen' in Clause 73 of the Articles, and inserting in its place the word 'five.'" "(3) That the Directors be authorised to raise £7,000 in addition to their powers in Clause 8 of the Articles, and to issue Six per Cent. Debentures or Bonds, namely, forty at £50 each, and fifty at £100 each, on the terms proposed by the solicitor, and to instruct him to prepare the debentures or bonds and the necessary documents." (Signed) A. Percy Smith, secretary. Clause 8 of the Articles now read:—"The Directors may forthwith, after the incorporation of the Company, from time to time, at their discretion, borrow or raise any sums of money for the purposes of the Company, upon such securities and upon such terms as they may think proper, but so that not more than £5,000 in addition to debentures be owing at any time without the sanction of a general meeting." The above-named Company was registered on January 8, 1890, with a capital of £22,000 in £10 shares. At the time of the last return, which was made up to November 25, 1891, and filed on December 5, 1891, 1,782 shares had been taken up, upon 1,162 of which the full amount had been called and paid, with the exception of £220; 620 shares had been issued as fully paid. Registered office: Albert Works, Graham-street, Birmingham.

PADDINGTON AND BAYSWATER ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The first annual return of the above-named Company, made up to January 4, 1892, was filed on January 18th following. The Company was registered on June 30, 1890, with a nominal capital of £1,000, divided into 900 ordinary and 100 founders' shares of £1 each, to supply the parish of Paddington and elsewhere with electric light, electricity, electrical currents, or force, heat, motive-power, or telegraphic, telephonic, or other means of communication. At the time of making-up seven founders' shares had been taken up, all of which were issued and considered as fully paid. The original subscribers are the only shareholders. No agreement for the acquisition of any business, plant, contracts, &c., have, as yet, been filed. Registered office: 13, Victoria-street, Westminster, London, S.W.

PROVINCIAL ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The first annual return of the above-named Company, made up to January 4, 1892, was filed on January 18, 1892. The Company was registered on June 28, 1892, with a nominal capital of £1,000 divided into 900 ordinary and 100 founders' shares of £1 each, to carry on, either in the provinces of Great Britain or elsewhere, the trade or business of electric lighting. At the time of making up seven founders' shares had been taken up, all of which, however, were issued and considered as fully paid, the original subscribers being the only shareholders. No agreements for the taking over of any businesses, plant, contracts, &c., have as yet been filed. Registered office: Westminster Chambers, 5, Victoria-street, Westminster, London, S.W.

PUTNEY AND HAMMERSMITH ELECTRIC LIGHT AND POWER SUPPLY (LIMITED).—The first annual return of the above-named Company, made up to January 4, 1892, was filed on January 18th following. The Company was registered on June 28, 1890, with a capital of £1,000, divided into 900 ordinary and 100 founders' shares, as the "Stamford Hill, Tottenham, and Edmonton Electric Light and Power Supply (Limited)," which name, however, was by special resolution passed June 3, 1891, and duly confirmed on June 24, 1891, changed to its present title. At the time of making up, seven founders' shares had been taken up, upon which, however, the full amount had been considered as paid. The original subscribers are the only shareholders. Registered office: Westminster Chambers, 5, Victoria-street, Westminster, S.W.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Mr. Emile Garcke has resigned the position of Managing Director of this Company, but retains his seat on the Directorate. Messrs. J. S. Raworth and R. P. Sellon have been appointed general managers, and Mr. W. Geipel is now superintending engineer.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended January 24th amounted to £811, as against £743 for the corresponding period of 1891, an increase of £68. The total receipts to date, from January 1, 1892, are £2,827, against £2,627 in the corresponding period of 1891, an increase of £200.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—At a meeting of the Directors held on Wednesday, the audited accounts for the half-year to December 31st were submitted, and it was resolved, after providing for the dividend on the preference shares, to recommend the payment of a dividend on the ordinary at the rate of 8 per cent. per annum, free of income tax.

Digitized by Google

EASTERN TELEGRAPH COMPANY (LIMITED).—This Company notify that the coupons on their Five per Cent. Debentures, due February 1st next, will be paid on and after that date at the banking house of Messrs. Glyn, Mills, Currie and Co., 67, Lombard-street, E.C. Coupons should be left at the bank three clear days for examination.

EASTERN AND SOUTH-AFRICAN TELEGRAPH COMPANY (LIMITED).—This Company announce the payments by warrants on February 1st next of interest for the half-year ending January 31st on their Four per Cent. Mortgage Debentures. The transfer books of the Company will be closed from January 29th to February 1st, both days inclusive.

HASTINGS AND ST. LEONARD'S-ON-SEA ELECTRIC LIGHT COMPANY (LIMITED).—The annual meeting of this Company was held on Tuesday, when a dividend at the rate of 7½ per cent. was declared for the past year. It was mentioned that, in order to meet the increased demand for the electric light, an extension of the plant was again necessary, and an additional issue of shares would be shortly offered to the shareholders. Mr. Hammond, who is largely interested in the Company, wrote a letter which was read to the meeting, in which he congratulated his fellow shareholders upon the favourable position of the Company. The retiring Directors—Mr. H. M. Baker, jun., and Mr. G. Roddis—were re-elected.

NEWCASTLE-UPON-TYNE ELECTRIC SUPPLY COMPANY (LIMITED).—The annual general meeting of this Company was held on Monday, at the Station Hotel, Newcastle, when the report and balance-sheet were adopted, and a dividend at the rate of 4 per cent. per annum was declared for the year ending December 31, 1891.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 716.—Vol. XXVIII. FRIDAY, FEBRUARY 5, 1892. PRICE SIXPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

To say that a large audience was enchanted by the long-expected lecture of Mr. Nikola Tesla on Wednesday night is no exaggeration; for as soon as he grasped his long glass tubes they glowed with softened splendour, as, magician-like, he waved them over his head, and little bulbs of glass with phosphorescing powder gleamed with a weird, if not ghastly, radiance when merely hung on his finger tip. Vainly did the unscientific members of the audience whisper to their neighbours, "How is it done?" And in his enthusiasm the lecturer, who seemed to love his wonderful lamps and globes, forgot to give an explanation. The more initiated flinched at the ominous crackle of the high-pressure discharges, and looked with some apprehension at a wooden box in which a magnetic interrupter was enclosed, and from which flames rose when the current was turned on. But the flames were shut down with an ordinary wooden lid, and the spluttering terminals shot out angry discharges at an iron clamp which the lecturer presented to it when he wished to convey a few hundred thousand volts through his body to a vacuum tube.

The apparatus used by Mr. Nikola Tesla is of the simplest description, but the arrangement of the subsidiary parts is complicated, and the adjustments are numerous and difficult to make. The high-frequency dynamo, which was placed in the dynamo-room of the Royal Institution, is most remarkable for its unsophisticated and plain design. It consists of a stationary armature, about 30 inches diameter, with 380 inwardly projecting coils, like those of a Parker alternator. A thin iron disc, like a fine-pitch gear wheel, is provided with 380 tiny magnets connected-up in series, runs with very small clearance, and generates a current with some 13,000 periods per second. This dynamo and several of the more characteristic experiments were described and illustrated in *The Electrician*, Vol. XXVII., p. 332. But no illustrations can convey an idea of the beautiful effects to those who have not seen them; and no report of the lecture can give to those who were not present, such an insight into Mr. Nikola Tesla's attractive personality as it was the privilege of his audience to enjoy.

The audience which gathers at the meetings of the Institution of Electrical Engineers is, probably, the most youthful of any scientific society; but several of the well-known men who often attend and take part in the proceedings are not members of the Institution. The Institution of Civil Engineers not only offers admirable accommodation, but provides a few members who contribute very usefully to the discussions. Some of these have been startled to find that their prerogative as members of the older Institution was of no avail for gaining admission to Mr. Nikola Tesla's lecture, and had to beg for tickets from members of the Institution of Electrical Engineers. That these tickets could be used for admitting strangers to the theatre of the Royal Institution came as a surprise when announcement was made to this effect after Prof. Ayrton's address; but this hope was rudely shattered by a circular, dated February 1st, which withdrew this privilege. As a last resource, several country members were appealed to by telegraph, and were good enough to send their post cards to their more fortunate London friends. By a fortunate combination of circumstances the theatre was just full, and no one was turned away. We understand that the Institution of Civil Engineers can accommodate only 400, and that the audience on Wednesday numbered about 800.

Some rather severe criticisms were made by *The Spectator* a few months ago on the habit, into which some scientific men are apt to fall, of "taking the public into their confidence, making known to it discoveries that are as yet only half known to themselves, and building upon the basis of those discoveries a bewildering fabric of conjectural possibilities." Criticism of such "fairy tales" is, no doubt, sometimes justifiable, but we see little reason for being severe. *The Spectator* remarked, in the article from which we recently gave extracts in our "Notes" columns, that its ignorant mind thus became confused with wild conjectures. If the science, so far as it goes, is correct, and the conjectures which go beyond, are fairly logical, such dissertations have a Jules Verne-like romance, and harmlessly amuse the public with ideas of these "half-baked notions" with which some thinkers are busying themselves.

To this kind of literature Prof. Crookes makes a large contribution in this month's *Fortnightly Review*. Ether vibrations, especially those of greater wave length than light, are discussed. The details are perhaps accurate enough for general readers, but the initiated will discover one or two slips. Beings are imagined who have eyes which are "sensitive to the vibrations concerned in electric and magnetic phenomena." "Glass and crystal would be among the most

Digitized by Google

opaque of bodies. Metals would be more or less transparent, and a telegraph wire through the air would look like a long narrow hole drilled through an impervious solid body. A dynamo in active work would resemble a conflagration; whilst a permanent magnet would realise the dream of mediæval mystics, and become an everlasting lamp with no expenditure of energy or consumption of fuel." There seems to be some confusion here. Surely HERTZ transmitted his vibrations through air, and screened them by metal sheets. The idea of comparing a conductor to a hole in a solid substance is connected with a rather barbarous but none the less abstruse theory of fluid currents. The longest wave length to which these imaginary eyes are sensitive is not given; but, as far as we are aware, no remarkable ether vibrations emanate from any dynamos but alternators; and the wave length of these is measured in thousands of miles. The most unwarrantable speculation is the one about the blazing magnet. The permanent magnet throws out no oscillations of any kind that have ever been published; and if Prof. CROOKES has any private information about them, we should like to learn what it is. Prof. FITZGERALD, at the last meeting of the Physical Society, aptly compared the continuous production of ether vibrations to the blowing of a whistle, and the snap of a Leyden jar to the drawing of a cork; but what such analogue is to be found for the passive condition of a permanent magnet? Electric whirls round magnetic lines of force are indeed alluded to in Prof. OLIVER LODGE'S "Modern Views;" but even if these be considered as causes in the Ampèrian sense, and not effects, we still have no Hertzian vibrations.

AFTER quoting largely from "Modern Views" Prof. CROOKES says: "Could we construct Leyden jars of molecular dimensions, Prof. LODGE considers the rays might fall within the narrow limits of visibility." This statement tends to confirm a rather erroneous interpretation which has been placed upon the original words. Prof. LODGE calculated that to produce waves 25 millionths of an inch long "the necessary circuit must have a self-induction in electro-magnetic units, and a capacity in electrostatic units such that their geometric mean is 10^{-5} centimetre. This gives us at once something near atomic dimensions for the circuit, and suggests immediately that those short ethereal waves which are able to affect the retina, and which we are accustomed to call 'light,' may be really excited by electrical oscillations or surgings in circuits of atomic dimensions." But the diameter of a molecule, or as it has been more cautiously expressed, the mean distance between the centres of contiguous molecules, is probably less than 2×10^{-7}, and greater than 10×10^{-9}. Molecules, according to the present state of knowledge, are much too small to make good Leyden jars for the cheap generation of light; and, as is clearly stated on p. 267 of "Modern Views," it can be calculated that the oscillation of an atomic charge would give rise to only ultra-violet rays.

THE two most recent and by no means least interesting additions to this subject are the suggestion that the merely mechanical vibrations of a molecule are more comparable with light undulations, and that examples of bodies which are actually of the dimensions suitable for electric oscillations are to be found in the rods and cones of the retina.

Aachen.—The erection of the central station at Aachen has been entrusted to Messrs. Schuckert and Co., of Nurnberg.

Personal.—Mr. T. Parker, of the Electric Construction Corporation, has been elected a Fellow of the Royal Society of Scotland.

The Bakerian Lecture.—The delivery of this lecture has been fixed for March 17th, and Prof. James Thomson has been invited to deliver it.

Royal Institution.—Lord Rayleigh will on Saturday (February 13th) begin a course of three lectures on "Matter: at Rest and in Motion."

Telephone in Italy.—A line of telephone, thirty miles long, the first that unites two Italian cities, has been opened between Milan and Pavia.

Electric Lamps for Omnibus Inspectors.—The London General Omnibus Company has supplied all their ticket inspectors with small electric lamps.

Burnley.—The electric lighting canvass having been satisfactory, it has been decided to engage an electrical engineer, with a view to advising the Corporation as to the best system to be used.

Dresden.—The first electric tramway in Dresden will be laid down during the summer. It will extend from the Schlossplatz to Loschwitz, and is to be worked by Messrs. Siemens and Halske.

Toronto.—The chief electrician of the Toronto Electric Light Company, while passing in the vicinity of a large dynamo on Sunday night, accidentally completed the circuit, and was severely injured.

Johannesburg.—The Johannesburg Lighting Company have installed some arc lights in the principal streets of Johannesburg, and as soon as the additional capital required can be raised will commence private lighting.

Heilbronn.—Since the 6th of January tests have been made on the line for the high-pressure transmission of power between Lauffen and Heilbronn, and it is expected that the ordinary working will now shortly be started.

Bristol.—At a recent meeting of the Town Council, it was decided, upon the report of the Electrical Committee, to pile the whole of the site of the new central station, instead of the walls and chimney stack only, at a cost of £9,659.

Royal Society.—At the Council Meeting of the Royal Society on January 21st, no fewer than ten deaths were announced, seven Fellows and three Foreign Members. The average number of deaths for the entire year is fifteen.

The Yokohama Central Station.—Amongst the buildings which suffered from the earthquake shocks which occurred in Japan on October 28th was the station of the Electric Lighting Company. The station was practically destroyed.

Dublin.—The Town Clerk of Dublin has been directed to convey to the Electrical Engineering Company the desire of the Corporation that all their material, as far as possible, used in the city electric light works should be procured in Ireland.

The Waterloo and City Railway.—At a special general meeting of the London and South-Western Railway Company, held yesterday, it was resolved to approve of the Bill to be laid before Parliament authorising the construction of this railway.

Electric Traction in Belgium.—The Belgian Minister of Railways has caused a report to be drawn up on the results obtained on the electric lines at Vevey-Montreux, Moedling-Hinterbrühl, Blackpool, and other places, with the object of seeing what advantages could be obtained by the adoption of electric traction on railways.

Digitized by Google

Portsmouth.—The Town Council has revoked its previous decision to light the town with electricity on the low-pressure system, and has adopted a new high-pressure scheme, estimated to cost £38,000. An amendment for deferring the scheme until the question of using tidal power for machinery was considered was lost by the Mayor's casting vote.

Physical Society's Report.—On p. 329 of our last issue, second column, line 5 from bottom, *for* $Q = Q_0 \epsilon^{-r/L\,t} \cos 2\pi t/T$ *read* $Q = Q_0 \epsilon^{-\frac{r\,t}{L}} \cos \frac{2\pi t}{T}$. Line 4 from bottom *for* $\epsilon^{-r/L\,t}$, *read* $\epsilon^{-\frac{r\,t}{L}}$.

Oldenburg.—The lighting of the ministerial buildings at Oldenburg will soon be at work. The job has been in the hands of Messrs. Schuckert and Co., who have put down two 100 H.P. turbines to be driven by the river Hunte. Sufficient power will be available to light the palace, the castle, and the theatre, but at present the ministerial offices and the bank only are to be lighted by electricity.

Standards of Light Committee.—The following is a list of the names of the Committee appointed by the Board of Trade to inquire into and report upon the subject of the standards to be used for testing the illuminating power of coal gas:—Mr. W. J. Dibden, Prof. E. Frankland, F.R.S, Mr. H. E. Jones, Mr. George Livesey, Prof. Wm. Odling, F.R.S., Mr. George Rose-Innes, Mr. W. J. Russell, F.R.S., Mr. G. C. Trewby, and the Gas Referees; Prof. Vivian B. Lewes being secretary.

An Electric Mail Car.—On the St. Louis and Suburban Electric Railway there is now in successful operation a United States mail car, which makes regular trips over the entire line, distributing and collecting the mail at the different railway stations. This car is of the same length as an ordinary steam railway mail car, and is equipped with double trucks with 36-inch wheels, a Thomson-Houston motor of 15-horse power capacity being connected to each truck. A very high speed is attained, and the delivery and collection of mails is made without stopping the car.

Copper.—Although the stock of copper in England and France and afloat was smaller at the end of January than it had been at the same date for three years previously, the price is considerably lower. According to Messrs. H. R. Merton and Co.'s statistics, the stock on January 31, 1892, was 57,462 tons, as against 61,396 tons in 1891, 95,714 tons in 1890, and 109,528 tons in 1889. Yet the price this year was £44. 12s. 6d. per ton, as compared with £52. 12s. 6d. per ton, £48. 17s. 6d. per ton, and £77. 10s. per ton on the same day in the three preceding years.

Obituary.—The death is announced of Mr. Thomas Wood Eason, Superintendent of the Dublin Telegraph Department. Thirty-five years ago he entered the service of the old Magnetic Telegraph Company in his native city of Cork; and at the time of the transfer of the telegraphs to the State in 1870 he was appointed Superintendent of the Belfast Telegraph Department, a position which he filled with marked ability. Subsequently, in 1882, on the chief post of the Dublin telegraph branch becoming vacant, Mr. Eason was appointed thereto, and he continued to hold it until his death.

The Magnetic Properties of Liquid Ozone.—At the meeting of the Royal Society on December 17, 1891, the following letter was read from Prof. Dewar:—

Royal Institution, December 17, 1891.

Dear Sir William Thomson: I had intended coming to the Society, in order to make a further communication with regard to the magnetic and other properties of liquid oxygen; but I am confined to the laboratory, owing to difficulties with regard to the progress of such investigation. In the meantime it may interest the Fellows to know that I have examined the properties of liquid *ozone* in the magnetic field, and find it also highly attracted. I hope to make a detailed communication very soon to the Society. JAMES DEWAR.

Frictional Electricity.—From a series of experiments made a short time ago, Prof. Wesendonck, of Berlin, inferred that dustless air, in friction with metals, does not generate electricity. But carbonic acid, under like conditions, readily gave a charge, and this was thought to be due to cloud-formation in the gas streaming out of the vessel which had held it in liquid form, the small water-particles charging the metal by friction. Further experiment has seemed to confirm this view. Prof. Wesendonck concludes that gaseous carbonic acid is not capable of generating electricity by mechanical friction on metal.

Mining Operations by Electricity.—Considerable interest, says the *Newcastle Journal*, is being evinced in mining circles generally as to the result of an important electric mining installation at one of the Earl of Durham's collieries, which, when finished, will be the largest and most complete electric mining plant as yet erected in this country. The operations to be effected consist of electric haulage, winding, pumping, lighting, signalling, telephoning, &c. The contract is being carried out by Messrs. D. Selby, Bigge, and Co., of Newcastle-on-Tyne, the machinery being built for them by Messrs. W. T. Goolden and Co.

Association Suisse des Electriciens.—We are in receipt of the "Annuaire" of this Association for 1892. In addition to the information usually given in publications of this kind, viz., a list of members of the Association, and its rules and regulations, there is a list of the leading Swiss electrical firms, together with telegraphic, telephonic, and electric lighting statistics; and a number of Federal laws bearing on electrical matters and on patents. The volume concludes with the report of a Committee of the Association with reference to the nationalisation of the waterfalls of Switzerland—a burning question in that fortunate country.

A New Launch Charging Station.—A new electric launch charging station is now being built at Eel-pie Island, Twickenham, for Mr. W. S. Sargeant, who will shortly transfer from Strand-on-the-Green, Chiswick, the business he there carries on as steam and electric launch builder, to Eel-pie Island. Here it will be conducted under the style of the Thames Electric and Steam Launch Company, and for this purpose large works are now being erected on the island. Several orders for new electric launches have been booked, one being for a boat 75ft. long, 13ft. beam, and draught aft 3ft. 6in. This will be larger than the "Viscountess Bury," which at present is the largest electric launch in the world.

Telegraphing by Electrostatic Induction.—A patent has just been granted to Mr. Edison for a system of transmitting signals electrically without the interposition of connecting wires. Several claims are made, but the principal one is the following:—"I claim as my discovery means for signalling between stations separated from each other, consisting of an elevated condensing surface or body at each station, a transmitter operatively connected to one of said condensing surfaces for varying its electrical tension in conformity to the signal to be transmitted, and thereby correspondingly varying the tension of the other condensing surface, and a signal receiver operatively connected to said other condensing surface, substantially as described."

A Four Years' Electrical Engineering Course.—An undergraduate course of four years in electrical engineering has been established in the School of Mines, Columbia College, in addition to the present two-year post-graduate course which has been in successful operation for several years. There will thus be two complete courses in electrical engineering in New York. The latter course is for graduates of scientific schools and colleges, and is entirely devoted to electrical engineering proper, the students having already passed the necessary preparatory studies in mathematics, physics, chemistry, mechanics, drawing, &c. This course is found to give the most excellent results by reason of the maturer years and better training of post-graduate students.

The Development of Electric Tanning.—According to *La Lumière Electrique* several French tanners have adopted the electric tanning process, but have not made the fact public "for fear of displeasing a clientèle always distrustful of new methods." The Société Brion et Dupré is known to employ six drums, capable of an annual output of 600 tons of tanned hide. In Portugal there are two electric tanneries at work, at Porte and Braga, having an annual output of 700 tons of tanned hide; and in Madagascar an electric plant is being set

Digitized by Google

up. In Brazil, at Boa Vista, some eight miles from Rio de Janeiro, there is an electric tannery covering about 13 acres, and possessing no less than 100 drums. The annual output of the Boa Vista plant will ultimately be about 70,000 tons.

Electric Light Signalling Experiments.—Experiments are being carried out on board the "Defiance" at Devonport with arrangements for night signalling by means of electric lights placed at the masthead. The experiment has frequently been tried, but hitherto with only partial success, owing to the difficulty of rendering the flashes distinct from each other, the lamps continuing to exhibit a faint glow for some time after the electric current has been shut off. Owing to this disadvantage signalling by electric lamps can at present only be carried out at the rate of less than 50 signals per minute, which is not found to be sufficiently rapid. In the experiments in question incandescent lamps are used, and the connection is made and cut off from the deck with a series of shutters actuated by electro-magnets.

Gas Concessions and Electric Lighting in France.—The French electrical papers chronicle two decisions of considerable importance to electric lighting enterprise in France which have just been rendered by the Conseil d'État. These decisions are based upon the terms of the concessions granted by the municipalities of Montluçon and Saint Etienne to the local gas companies, concessions of much the same monopolistic character as that granted by the municipality of Sedan, the contravention of which recently landed that body in a lawsuit, and the payment of 14,000fr. damages. (*The Electrician*, November 13, 1891, p. 23 and p. 26.) The Conseil d'État held that the concessions granted to the gas companies of Montluçon and Saint-Etienne gave them the monopoly of the street lighting and the exclusive right of making use of the roads for the distribution of illuminants, whether gas or electricity. The Conseil d'État consequently cancelled the electric lighting concessions.

The Repulsion and Rotation produced by Alternating Electric Currents.—In a Paper on this subject, communicated to the Royal Society in December last, Mr. G. T. Walker, of Trinity College, Cambridge, gives some expressions for calculating the intensities of the force and couple respectively experienced by a ring of metal placed over and by a ring of metal pivoted over an alternating electro-magnet. He also investigates the well-known experiment of Professor Elihu Thomson, in which a sheet of copper is placed so as to half cover an alternating magnetic pole, and a hollow copper sphere is laid upon the plate; the electro-magnetic action producing a couple sufficiently powerful to overcome friction and to spin the sphere round. According to Mr. Walker, the sphere spins round in virtue of the fact that the currents induced in the copper plate "do not coincide in phase with those of the magnet, and not (as has been stated) because it acts as a screen, and renders the field unsymmetrical. Were the plate a perfect conductor, it would be a perfect screen, but there would be no couple."

Dynamo Speed Regulation.—Owing to the variations of load and water pressure, most turbines, says Herr Adolf Zoeppritz in the *Elektrotechnische Zeitschrift* for January 1st, are liable to considerable variations of speed; and at some textile works at Heidenheim the following device has been adopted to maintain an approximately constant speed and quick automatic regulation of a turbo-dynamo. Between turbine and dynamo there is a coned countershaft, and the belt from the turbine is shifted along the cone by the action of a centrifugal governor attached to the turbine. Theoretically, there is no limit to this method, but practically the greater the difference between two successive speeds of the turbine the further the belt has to be moved, and the longer is the time which elapses before equilibrium is restored. Now, the speed of a lightly-loaded turbine varies less for a given change of load than that of one fully loaded; and hence at Heidenheim an 18H.P. turbine is used to run a 4H.P. dynamo. So that the device is only applicable where water power is superabundant.

Law of the Magnetic Circuit.—It is curious, remarks *Industries*, that nearly all electrical engineers think that magnetism follows Ohm's, or an analogous law. It really does not follow any such law. Ohm found by experiment that $E/C = R$. That is a definite law, R depending on the ratio of E and C, and not on their absolute value. The analogous magnetic "law" merely amounts to a definition. It is not a statement that the resistance is equal to the ratio of the "magneto-motive force" to the flux, as that is not the case. The resistance depends on the values as well as on the ratio of these quantities, so that we have only a definition left, with no underlying law whatever. Some say, "When there is a magneto-motive force and a flux we will call their ratio the magnetic resistance." The ratio of any two quantities may be given a name, but that does not provide any analogy to Ohm's law. Of course, it must not be forgotten that current and induction are both solenoidal, but solenoidal distribution is met with in so very many branches of physics that it affords no special analogy between current and induction in particular.

Arc-Light Carbons.—*L'Electricité* recently discussed in a brief article the ever-fascinating subject (for inventors) of improving the light-giving properties of arc-light carbons by the introduction of rare earths and of reducing the consumption of carbon to a minimum by striking the arc within a closed vessel containing some gas or other. The first commercially successful artificial carbons in France were those of Jacquelain, an assistant of Dumas, the chemist. Jacquelain carbons consisted of pure compressed carbon, obtained by decomposing some hydro-carbon oil. Then came the Carré carbons. Carré used crushed coke, from which all impurities were then eliminated by chemical washings. To obtain dense wood charcoal carbons Sidot and Gauduin heated the charcoal in a stream of bisulphide of carbon, chloride of carbon, or some hydro-carbon. These substances were split up by the heat, and gave up their carbon, which was left in the pores of the wood; the result being heavy carbons giving a sonorous metallic ring. Among the many attempts to produce a satisfactory arc light within a closed vessel were those of the engineers of the Paris Gas Company, the gas employed being ordinary illuminating coal gas. It was said at the time that the net result of these investigations went merely to show that coal-gas was consumed instead of carbon, so that no particular advantage was gained.

The Heat Radiation of Rarefied Gases under the Electric Discharge.—Herr Angström, says *Nature*, has been lately engaged in examining with a bolometer the heat radiation of various rarefied gases under the electric discharge. He confined himself to the stronger positive light, using cylindrical glass tubes, with lateral electrodes, and rock-salt plates at the ends. An accumulator of 800 Planté elements was the source of electricity. Briefly stated, the results are these:—With a given pressure the radiation is proportional to the intensity of the current. With constant current, the radiation does not vary while the pressure varies between 0·1 and 1·5mm., but at higher pressures it increases somewhat. With the same gas and pressure, the composition of the radiation is constant, and does not depend on the intensity of the current. With varying density of gas, the ratio of the intensity of radiation of

Digitized by Google

shorter wave lengths to that of the whole decreases with increase of pressure. (This ratio varied, *e.g*, from 46 to 15 per cent. in carbonic oxide between the above pressure limits.) Thus this ratio, at low pressures, reaches much higher values than in our ordinary light sources. The intensity of total radiation varies considerably in different gases, and stands in no simple relation to the molecular weight, nor to difference of potential in the gas; nor does it seem to depend on absorption of gas at ordinary pressure and temperature.

The Tramways of the United Kingdom.—The tramway system of this country, says the *Economist*, has latterly expanded very slowly. In 1889-90 the trifling addition to the mileage was more than counterbalanced by the disuse of lines which took place; and the Parliamentary report which has just been issued for the year ended June 30, 1891, shows that during the year the net addition to the mileage in England was only 15 miles; in Scotland and Ireland there was no growth whatever; whilst there was no increase in the number of tramway undertakings throughout the kingdom. In 1880, 368 miles of tramways were in operation in the United Kingdom; in 1890 the mileage was 948. In 1891 the total mileage was 963, the total capital authorised being £17,909,809, and the total capital expended £14,162,650, making the average cost per mile £14,707. The number of passengers carried during the year ended June 30, 1891, was 565,621,500, against 526,369,000 for the corresponding period, an increase of 7 per cent. The total number of cars is now 4,067, and of horses 29,002. The gross receipts increased during 1890-91 by over 6 per cent. to £3,429,686; this augmentation was, however, more than counterbalanced by the increase in working expenses, which rose from £2,402,800 to £2,630,929, an increase of 9 per cent., which reduced the net earnings to £798,757, making the percentage ratio $\frac{\text{net receipts}}{\text{capital expended}} = 5{\cdot}48$. It is interesting to note that the total "street railway" mileage of Canada and the United States is 11,029, of which electricity is responsible for 3,009 miles, the total number of cars being 36,517.

An Interesting Electrolytic Phenomenon.—In a communication recently made to the Académie Royale de Belgique, Prof. Lagrange and M. Paul Hoho describe some experiments made by them on a luminous and calorific phenomenon which takes place under certain conditions when a current is passed through an electrolyte. The phenomenon was first observed in 1844 by Foucault and Fizeau, and has subsequently also been investigated by Righi, Colley, Planté, and others. Prof. Lagrange and M. Hoho employed in one experiment a 10 per cent. solution of H_2SO_4, the positive electrode being of copper with 180 square cms. in the liquid, the negative electrolyte being a copper wire ¼mm. in diameter plunged into the electrode to a depth of ½mm. Current was obtained from a battery of accumulators. At first only the ordinary phenomena of electrolysis are observed; then, as the volts are increased, bubbling and boiling occur at the negative electrode, next intermittent arcs take place between wire and liquid, finally a luminous cylinder is formed having the copper wire for axis, the current then becomes steady, and the resistance very high. On plunging the wire further into the liquid, this series of phenomena can be reproduced. Much the same effects were produced with platinum, zinc, tin, iron, steel, and carbon electrodes of different diameters, with sulphuric acid solutions of different strengths, and with a chloride of sodium solution. The production of the luminosity is accompanied by an abnormal resistance which is localised round the negative electrode; with electrodes 29 cms. apart, practically all the fall of potential takes place within 5mm. of the negative electrode. The shape of the negative electrodes appears to have but little influence. Luminous effects can be made to occur also at the positive, but with some difficulty. It is, however, impossible to produce luminosity at both poles at the same time.

The Conductivity of Cast Steel.—In a recent article in *La Métallurgie*, M. Campredon gives some interesting particulars with regard to the conductivity of cast steel. He takes as his standard of comparison the electrical resistance of a wire 1mm. in diameter and 1 kilometre in length. Under these conditions copper comes out at 21 ohms, iron at 125 ohms. In the French telegraph contracts, it is stated that wires must be of charcoal iron, but soft steel wire can be substituted. The conductivity of soft steels is in direct relation to its chemical composition and its homogeneity. Tests of conductivity have been made with a certain number of coils whose chemical composition has also been determined. The chemical and electrical results are shown in the following table:—

No. of piece.	Carbon.	Silicium.	Sulphur.	Phosphorus.	Manganese.	Total Impurities.	Resistnce in ohms.
1	·090	·020	·050	·030	·210	·400	127
2	·100	·020	·050	·040	·240	·450	133
3	·100	·020	·060	·040	·260	·480	137
4	·100	·020	·050	·050	·310	·530	140
5	·120	·030	·070	·050	·330	·600	143
6	·110	·030	·060	·060	·350	·610	144
7	·120	·020	·070	·060	·380	·650	149
8	·120	·020	·070	·070	·400	·680	150
9	·110	·030	·060	·060	·490	·750	156
10	·140	·030	·060	·080	·540	·800	173

From this table it will be noticed that soft cast steel conducts much better in proportion to its degree of softness and purity, and that manganese is the element whose presence has the greatest influence. It is not sufficient that steel should be extra soft—it must also be perfectly homogeneous to be a good conductor. Cast steel which is pure, and only slightly manganesiferous, and contains less than 0·700 per cent. of foreign matters, runs off very hot, and consequently sufficiently homogeneous, has a resistance of less than 105 ohms when tested under conditions fixed in the contracts by the Minister of Telegraphs. Such a metal presents, moreover, those physical and mechanical properties which would permit of its being accepted with the same confidence as the earlier charcoal iron.

The South African and International Exhibition.—It is proposed to hold this Exhibition next September, at Kimberley, which is easily accessible by rail. The Cape Government Railway Department is cordially co-operating with the Exhibition, and will reduce the passenger fares and give special facilities to visitors by running special trains at greatly reduced prices. Electricity will play an important part, and will be used in lighting the buildings and grounds. Exhibits from abroad will be brought from any of the ports of the Colony in bond, carriage free, and will not be subject to duty unless they are sold. Diplomas and medals will be awarded to successful exhibitors in every department. The guarantee fund exceeds £17,000, and is expected to reach £20,000. It is proposed that the Exhibition shall remain open for three months. Charge will be made for space for all works sent for exhibition otherwise than by special arrangement. All the larger exhibits, or such as require special fittiugs, must be delivered not later than 15th August. Smaller exhibits can be delivered after that date, but not later than August 25, 1892. All exhibits must be arranged and ready for exhibition before September 1st. Awards will be given for the best electric generator and motor, having the highest commercial efficiency, strength, and simplicity of design, ease in operation, highest insulation, and capability of working in damp places without injury; for the best arc lamp; for the best arc dynamo; for the best incandescent dynamo; for the best electrical fittings. Intending exhibitors are informed that the British and Colonial Steam Navigation Company (Bucknall Bros.) are prepared to convey exhibits outwards at current rates, and bring back unsold exhibits (if any) free of charge, refunding outward charges. The Castle Mail Packets Company, the Union Steamship Company, the South African Steamship Company, the International Steamship Company, and the Clan Line offer special advantages. The London Executive Committee comprises—Sir Charles Mills, Sir Philip Cunliffe-Owen, Sir George Hayter Chubb, Sir Donald Currie, Mr. W. M. Farmer (Union Steamship Company), Mr. H. A. Hedley, Mr. E. P. Mathers, Mr. George J. S. Mosenthal, Mr. John Paddon, Mr. C. I. Posno (Chairman of London and South African Exploration Company), Captain Wisely (Castle Mail Packets Company). The honorary solicitors in London are Messrs. Bircham and Co., of 50, Old Broad-street; and the London manager is Mr. Lewis Atkinson, 3 and 4, Fenchurch-street.

WILLIAM EDWARD AYRTON, F.R.S.

Prof. W. E. Ayrton, born in 1847, is the son of the late Mr. E. N. Ayrton, a barrister, whose extremely reserved and somewhat repellant manner prevented "his taking the position as a public man for which his remarkable talents so well qualified him." For, as further stated in a long memoir from the pen of a leader at the equity bar, which appeared in the public press at the time of Mr. E. N. Ayrton's death, "He was in every way a remarkable man. . . . . Few men knew more than he did, or more thoroughly what he knew. He was an accomplished linguist and a critical scholar, while he was none the less a master in many departments of science, and was surpassed by few as a lawyer." . . .

Prof. Ayrton's earliest recollection is that of hearing seven different languages spoken at home, one particular language only being always used on each particular day of the week. But the only result of these unusual efforts that were made to give the child a mastery over languages was to develop a fondness for mathematics and science; so that while later on the lad felt a moral obligation to win classical prizes at school, he grew to detest the study of language, and loved to absorb himself in the solution of geometrical problems, and in the carrying out of optical and mechanical effects for a mimic theatre.

Having spent five years at University College School, he studied from 1864 to 1867 at the College under the late Prof. De Morgan, Dr. Hirst, and Prof. Foster, becoming, in the third year of his college course, assistant to the two latter. After gaining the Andrews Prize and the Andrews Scholarship for pure and applied mathematics, in addition to many minor prizes, his attention was turned to India from some ten students at the College coming to him to be prepared for the second examination for the Indian Government Telegraph Service. And after passing, with honours, the first B.A. examination at the London University, he entered the Indian Telegraph Service in 1867.

Coming out far above all the other candidates at the entrance examination, he was sent by the Secretary of State for India to study with Sir William Thomson in Glasgow, and on the result of the second examination in 1868 he was awarded a scholarship, with leave to stay in Europe on full pay to continue his electrical studies.

Proceeding ultimately to India he was appointed assistant to the late Mr. Schwendler, the electrical superintendent of the Indian Government Telegraph Department, and was engaged in introducing throughout the whole of British India a complete system of immediately determining the position of a fault by testing from the end of a telegraph line. In spite of the vast lengths of many of the Indian telegraph lines, on which there are no intermediate telegraph offices to be called in in case of a breakdown, the method of determining the position of faults by electrical testing from the end of the line was quite unused. Hence its introduction led to a great reduction in the average time of transit of a message, a result of great pecuniary importance. For the Indian Government decided that all messages sent between places east and west of India along the Eastern Company's cables, which had then just been laid, must be sent by land between Bombay and Madras, and that the submarine cable that the Eastern Company had arranged to lay round India from Bombay to Madras was unnecessary, and must not be laid. And as the Company based their appeal to the House of Commons against this decision on the bad working of the Indian land lines, it was of vital importance to the Government that they should be rapidly improved.

After having been made acting electrical superintendent, and appointed to take charge of the telegraph offices at Bombay and Calcutta, to enable him to aid in effecting these improvements, Mr. Ayrton returned in 1872 on leave to England, and was employed by the India Office on special duty in connection with the testing of insulators; for he had shown that the great leakage on some of the long Indian lines was due to the fact that a small percentage of the insulators were electrically porous in damp weather, although apparently quite free from flaws, even when examined with a microscope. He was also employed by Sir William Thomson and the late Prof. Fleeming Jenkin in the electrical testing of the Atlantic cable, then being constructed for the Great Western Telegraph Company at Millwall, and subsequently he was placed in charge of the cable-testing department at Mitcham on their behalf.

On the establishment of the Japanese Imperial College of Engineering in 1873, the largest English-speaking technical university of that day, he was offered the Professorships of Physics and Telegraphy, which he held until 1878, carrying out a number of experimental investigations with Prof. Perry, who had charge of the department of Mechanics. The physical laboratories at this college, constructed from Prof. Ayrton's designs, were fully described and illustrated in the *Builder* in 1880, being at that period among the finest in the world.

On Prof. Ayrton's return to England he was for some time adviser to the firm of Messrs. Latimer Clark, Muirhead and Company, whom he left to take in hand the work of the City and Guilds of London Institute, the rapid growth of which is sketched in his inaugural address recently delivered to the Institution of Electrical Engineers (see this and the last number of *The Electrician*).

Having assisted in developing the Finsbury Technical College out of a scheme for a mere trades school, he was in 1884 appointed Professor of Applied Physics at the City and Guilds of London Central Institution. In 1881 he was elected a Fellow of the Royal Society, and in 1889, a Member of Council; while the Royal Society is represented by him on the Council of Almoners of Christ's Hospital, and on the Board of Governors of the Imperial Institute. He has been a Secretary of the Mathematical and Physical Section, and is now a Member of the Council, of the British Association; has served as juror on various Exhibitions; was a Member of the Commission to the Frankfort Exhibition of last year; and is a Member of the Committee of Experts at the Crystal Palace Exhibition. Lastly, the Physical Society and the Institution of Electrical Engineers have now, for the first time, the same President—Professor Ayrton.

Dr. Wormell and he are joint editors of Messrs. Cassell's "Manuals of Technology," and one of the series, "Practical Electricity," already in its sixth edition, is from his pen, while, with Prof. Perry and others, he has published over one hundred Papers in the *Transactions* and *Proceedings* of the Royal Society, the Physical Society, the Institution of Electrical Engineers, &c., as well as contributing numerous articles to the technical and the general Press. His lecture on the "Electric Transmission of Power," given at the meeting of the British Association at Bath in 1888, was so much appreciated that, at the request of the town, this lecture was repeated to an audience of some 3,000, the first time in the history of the Association that one of their lectures has been repeated.

For several years the *Journal* of the Society of Telegraph Engineers was edited by him; and the present prosperous position of this Society took its start when, on his becoming the Chairman of the Editing Committee in 1878, he raised a loan of some eight hundred pounds to pay off the printer's debt and to enable the printing of the *Journal* to be placed on an economical basis.

Prof. Ayrton has been twice married. His first wife was Miss Chaplin, one of "the seven against Edinburgh," who, having been induced to spend several years at the University of that town, where they beat the men students on their own ground, were not allowed to take a degree, it being found out at the last moment that women students were contrary to the charter. She subsequently graduated as Doctor of Medicine in Paris, published numerous articles on Japan in the *Scotsman* and elsewhere, as well as a book on "Child Life in Japan," drawing many of the illustrations herself with the Japanese brush. But the great exertion connected with her medical and literary life, combined with the efforts she made throughout to improve the education and professional status of women, proved too much for her strength, for she died in 1883 at the early age of 36, leaving several unpublished manuscripts. Miss Marks, a certificated student of Girton College, Cambridge, and now a member of its Executive Committee, the friend of "George Eliot" and of the late Madame Bodichon, was married to Prof. Ayrton in 1885. The character of "Mirah" in "Daniel Deronda" is, we understand, drawn from Mrs. Ayrton; but the

Digitized by Google

novelist has doubtless invented many of the surroundings to heighten the dramatic effect.

Among the numerous researches of a purely scientific character which have formed, together with more practical matters, the subject of nearly a hundred Papers before the Royal Society, Physical Society, and the Institution of which he is the newly elected President, may be mentioned his investigations with Prof. Perry on the specific inductive capacity of gases, the contact theory of voltaic action, and a determination of v; while as an inventor his name, associated with that of Prof. Perry, is known all over the world in connection with direct-reading electrical measuring instruments. The pioneering labours in instrument making, the design of motors, and the development of the Telpher system at a time when electrical engineering was in its earliest infancy are apt to be overlooked, because they do not occupy a prominent position in modern work; but the Ayrton and Perry ammeters and voltmeters were invaluable, even in their crudest form, and hundreds of the oldest type are in daily use at the present time. The electric meter, of which larger numbers than any other are at work in this country, and which was independently invented by Dr. Aron, was patented by Profs. Ayrton and Perry in 1881. Differential gear was designed, but the patent was abandoned, partly because none were ever sold, and partly because it seemed foolish to have to wind up a clock when a motor can be turned by a current. The patent contained a claim describing the principle of the meter, which was subsequently invented by Prof. Elihu Thomson. The winding of voltmeters, the construction of the secohmmeter and the hot-wire instruments are branches of the same subject which have more recently received Prof. Ayrton's attention. Busily occupied himself, he succeeds in living more than one life by imparting to his assistants and to his advanced students a zeal for research by setting them to work on such important subjects as the working efficiency of secondary cells, and by presenting to the scientific world the result of their investigations.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(*Continued from page 301.*)

§ 57. **Application to the Current-Weigher.**—In this instrument the fixed and moveable coils have their planes parallel. Hence the value of M reduces to $M = G_1 g_1 + G_2 g_2 + G_3 g_3 + \ldots$ Let us make the fixed coil in two halves, at distance 2 B apart; and, as in § 49, send the current round these two halves in opposite directions. In this case, by § 54, we have, $G_1 = 0$, $G_2 = 6\pi A^2 B/C^5$, $G_3 = 0$, $G_4 = 10\pi A^2 B (B^2 - \frac{3}{4} A^2)/C^9$. Thus, when the suspended coil is at a distance b from the centre, we have,

$$M = \frac{6\pi A^2 B}{C^5} \times 2\pi a^2 b + \frac{10\pi A^2 B (B^2 - \frac{3}{4} A^2)}{C^9} \times 4\pi a^2 b (b^2 - \tfrac{3}{4} a^2) + \&c.$$

If $C = \sqrt{A^2 + B^2}$ is large compared with a and b the terms of this series soon become very small.

It is not M, however, which concerns us, but the variations of M. We find the force experienced by the small coil by differentiating M with respect to b. Thus the force per unit current in each coil is

$$\frac{dM}{db} = \frac{2\pi^2 A^2 a^2}{C^4} \left\{ 1 \cdot 2 \cdot 3 \frac{B}{C} + 3 \cdot 4 \cdot 5 \frac{B (B^2 - \frac{3}{4} A^2)}{C^5} (b^2 - \tfrac{1}{4} a^2) + \ldots \right\},$$

the expression used by Lord Rayleigh in discussing the best dimensions of a current-weigher.

Although this expression is very useful in enabling us to decide upon the best proportions for an instrument, it is not very well suited for numerical calculation. We shall, therefore, discuss some methods better adapted to this purpose.

§ 58. **Use of Neumann's Formula.**—We shall now make use of this formula to find the coefficient of mutual induction for a pair of coaxal circles. Let A, a be the radii of the circles, x the distance between their centres C, D (Fig. 50). Let any plane through the common axis cut the circles in P Q. Draw the radius D R, making an angle θ with D Q. Draw C K parallel and equal to D R, and join P K, K R, R P. Then

$$PK^2 = PC^2 + CK^2 - 2\,PC \cdot CK \cos\theta = A^2 + a^2 - 2Aa\cos\theta.$$

And $$PQ^2 = PK^2 + KR^2 = A^2 + a^2 + x^2 - 2Aa\cos\theta.$$

By Neumann's formula we have $M = \iint ds\, ds' \cos\epsilon \cdot 1/r$, where ϵ is the angle between the two elements. The angle between the element at R and the element at P is evidently θ. Thus $\epsilon = \theta$. One integration can be effected at once, for the value of $ds \int ds' \cos\epsilon \cdot 1/r$ (the element ds' belonging to the circuit Q R and the integration extending all round that circuit) is independent of the actual position of P on the circle P T. The integration round the circle P T, therefore, gives us

$$M = 2\pi A \int ds' \cos\epsilon \cdot 1/r.$$

Now, $ds' = a\,d\theta$, $\epsilon = \theta$, and $r^2 = A^2 + a^2 + x^2 - 2Aa\cos\theta$, so that

$$M = 2\pi A \int_0^{2\pi} \frac{a\cos\theta\, d\theta}{\sqrt{A^2 + a^2 + x^2 - 2Aa\cos\theta}}.$$

Having got this formula, the question arises what are we to do with it? The integral cannot be expressed in terms of any finite algebraic function. Under certain circumstances we can express the integral in terms of an infinite series, but in all cases we can express it in terms of the transcendental functions known as elliptic integrals.

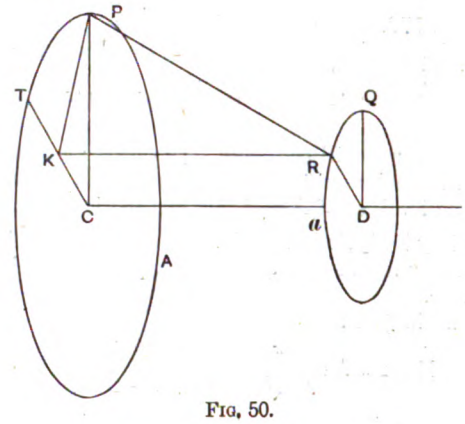

FIG. 50.

§ 59. **Series for M.**—We shall write $\rho^2 = A^2 + a^2 + x^2$ for brevity. We can write this expression in the form

$$M = 2\pi A a \int_0^{2\pi} \frac{\cos\theta\, d\theta}{\sqrt{\rho^2 - 2Aa\cos\theta}} = \frac{2\pi A a}{\rho} \int_0^{2\pi} \cos\theta \left\{ 1 - \frac{2Aa}{\rho^2} \cos\theta \right\}^{-\frac{1}{2}} d\theta.$$

So that if $2Aa$ is *small compared with* ρ^2, we can expand by the binomial theorem, and find

$$M = \frac{2\pi A a}{\rho} \int_0^{2\pi} \cos\theta \left\{ 1 + \frac{1}{1} \frac{A a}{\rho^2} \cos\theta + \frac{1 \cdot 3}{1 \cdot 2} \left(\frac{A a}{\rho^2}\right)^2 \cos^2\theta + \frac{1 \cdot 3 \cdot 5}{1 \cdot 2 \cdot 3} \left(\frac{A a}{\rho^2}\right)^3 \cos^3\theta + \ldots \right\} d\theta$$

We notice that all the *odd* powers of $\cos\theta$ vanish on integration, and that $\int_0^{2\pi} \cos^n\theta\, d\theta = 4 \int_0^{\frac{\pi}{2}} \cos^n\theta\, d\theta$, where n is any *even* whole number.

We thus find

$$M = \frac{8\pi A^2 a^2}{\rho^3} \int_0^{\frac{\pi}{2}} \left\{ \cos^2\theta + \frac{3 \cdot 5}{2 \cdot 3} \left(\frac{A a}{\rho^2}\right)^2 \cos^4\theta + \frac{3 \cdot 5 \cdot 7 \cdot 9}{2 \cdot 3 \cdot 4 \cdot 5} \left(\frac{A a}{\rho^2}\right)^4 \cos^6\theta + \right\} d\theta$$

Digitized by Google

Again, it is well known that when n is an even whole number

$$\int_0^{\frac{\pi}{2}} \cos^n\theta\, d\theta = \frac{n-1}{n}\cdot\frac{n-3}{n-2}\cdots\frac{3}{4}\cdot\frac{1}{2}\cdot\frac{\pi}{2}.$$

Hence,

$$M = \frac{2\pi^2 A^2 a^2}{\rho^3}\left\{1+\frac{3}{2.3}\cdot\frac{3}{4}\left(\frac{A\,a}{\rho^2}\right)^2 + \frac{3.5.7.9}{2.3.4.5}\cdot\frac{5.3}{6.4}\left(\frac{A\,a}{\rho^2}\right)^4 + \ldots\right\}$$

Again, $\rho^2 = A^2 + a^2 + x^2$; therefore $\rho\, d\rho = x\,dx$ and $d\rho/dx = x/\rho$.
Hence, $d\,M/dx = d\,M/d\rho \times d\rho/dx = x/\rho \times d\,M/d\rho$.

Hence the attraction between the two coils for unit current in each is

$$X = -\frac{d\,M}{dx} = \frac{6\pi^2 A^2 a^2 x}{\rho^5}\left\{1+\frac{3.5}{2.3}\cdot\frac{1}{4}.7\left(\frac{A\,a}{\rho^2}\right)^2 + \frac{3.5.7.9}{2.3.4.5}\cdot\frac{5}{6.4}.11\left(\frac{A\,a}{\rho^2}\right)^4 + \ldots\right\}$$

Taking, as in § 47 A = 50cm., a = 10cm., x = 25cm., we have

$$\rho^2 = 3225\ A, \quad a/\rho^2 = \cdot1550388, \text{ so that}$$

$$M = 26\cdot9439\left\{\begin{matrix}1+\cdot0450694+\cdot0028437+\cdot0002036\\ +\cdot0000156+\cdot0000012+\cdot0000001\end{matrix}\right\} = \begin{matrix}28\cdot2418\\ \text{cm.}\end{matrix}$$

This approximation includes all the terms up to and including the one containing $\left(\frac{A\,a}{\rho^2}\right)^{12}$. By the rough method of § 47 we found M = 28·2491. Again,

$$X = \cdot6266236\left\{\begin{matrix}1+\cdot1051619+\cdot0104271+\cdot0010182\\ +\cdot0000988+\cdot0000096+\cdot0000009\end{matrix}\right\} = \cdot699761$$

dynes per unit current in each coil. By the rough method we found X = ·6779. The successive terms have been written down in order to show the rapidity with which the series converge under favourable conditions.

An inspection of the series for M and $d\,M/dx$ will show that if $A\,a/\rho^2$ has a value more than twice as large as in the above example, the series will converge very slowly; and that if $A\,a/\rho^2$ becomes a little larger still, the series cease to converge at all. But for small values of $A\,a/\rho^2$ this method is convenient.

§ 60. M by Elliptic Integrals.—We shall now show how to calculate M by means of a table of Elliptic Integrals calculated by Legendre.

We found in § 58 that

$$M = 2\pi A a\int_0^{2\pi}\frac{\cos\theta\, d\theta}{\sqrt{A^2+a^2+x^2-2Aa\cos\theta}}.$$

Putting $c^2 = 4Aa/\{(A+a)^2+x^2\}$ and $\theta = 2\psi$, and remembering that $\cos\theta = 2\cos^2\psi - 1$, we find

$$M = 4\pi c\sqrt{Aa}\int_0^{\frac{\pi}{2}}\frac{2\cos^2\psi - 1}{\sqrt{1-c^2\cos^2\psi}}\,d\psi$$

Putting $\psi = \pi/2 - \phi$ we have

$$M = 4\pi c\sqrt{Aa}\int_0^{\frac{\pi}{2}}\frac{2\sin^2\phi - 1}{\sqrt{1-c^2\sin^2\phi}}\,d\phi$$

$$= 4\pi\frac{\sqrt{Aa}}{c}\int_0^{\frac{\pi}{2}}\frac{-2(1-c^2\sin^2\phi) - (c^2-2)}{\sqrt{1-c^2\sin^2\phi}}\,d\phi$$

$$= 4\pi\sqrt{Aa}\left\{\left(\frac{2}{c}-c\right)\int_0^{\frac{\pi}{2}}\frac{d\phi}{\sqrt{1-c^2\sin^2\phi}} - \frac{2}{c}\int_0^{\frac{\pi}{2}}\sqrt{1-c^2\sin^2\phi}\,d\phi\right\}$$

The two definite integrals in this expression are called the Complete Elliptic Integrals of the First and Second Kinds, and are denoted by F (c) and E (c). They are simply functions of c. Thus, the First Integral is $F(c) = \int_0^{\frac{\pi}{2}}\frac{d\phi}{\sqrt{1-c^2\sin^2\phi}}$, and the Second $E(c) = \int_0^{\frac{\pi}{2}}\sqrt{1-c^2\sin^2\phi}\,.\,d\phi$.

These integrals are of very great importance in many respects. They have been calculated by Legendre, and their values will be found in Table I., Vol. II., of his "Traité des Fonctions Elliptiques," Paris, 1826. For convenience they are not tabulated according to c, but c is put equal to sin γ. The tables then give the values of log E (sin γ) and log F (sin γ), for all values of γ from 0deg. to 90deg. by intervals of 6′. The values are given to *at least* 12 places of decimals.

We can now write $M = 4\pi\sqrt{A\,a}\,\{(2/c - c)\,F(c) - 2/c\,E\}$. In both Maxwell and Mascart & Joubert this formula is given with the wrong sign. Maxwell, Vol. II., gives a table of the values of

$$\log\frac{M}{4\pi\sqrt{Aa}} = \log\{(2/c - c)\,F(c) - 2/c\,E(c)\}$$

for values of $\gamma = \sin^{-1}c$ from 60° to 89° 54′ by intervals of 6′.

As an example we will calculate, by the aid of Legendre's tables, the value of M for the case taken in §§ 47, 59.

Here

$$\sin\gamma = c = \frac{2\sqrt{500}}{\sqrt{4225}} = \cdot68801 \qquad \gamma = 43°\ 28'.42,$$

so that $2/c - c = 2\cdot218867$ $\quad 2/c = 2\cdot906888$.

From Legendre's Tables we find that when $\gamma = 43°\ 28'\cdot42$

$$\log E(\sin\gamma) = \cdot1347919, \qquad \log F(\sin\gamma) = \cdot2629611,$$

giving $M/\{4\pi\sqrt{Aa}\} = \cdot100510$, whence M = 28·24257cm., very nearly the same as we found before.

A study of the tables of these functions reveals the fact that this process is not very well adapted for the calculation of M, when γ is less than 40°, the reason being that the two quantities whose difference we have to find are then nearly equal. But these cases can generally be treated satisfactorily by the series method. It may be useful to note that if r_1 and r_2 are the greatest and least values of r, the distance between two points one on one circle, and one on the other, then $\cos\gamma = r_2/r_1$.

§ 61. Value of the Attraction.—If we wish to find the attraction between the two coils when unit current flows in each we must find the value of $X = -d\,M/dx$. It can be shown that

$$\frac{d\,M}{dx} = \frac{\pi x\sin\gamma}{\sqrt{A\,a}}\left\{2\,F(\sin\gamma) - (1+\sec^2\gamma)\,E(\sin\gamma)\right\}.$$

Lord Rayleigh gives a table of the values of

$$\sin\gamma\,\{2\,F(\sin\gamma) + (1+\sec^2\gamma)\,E(\sin\gamma)\}$$

for values of γ ranging from 55° to 70° by intervals of 6′. (See "Electrochemical Equivalent of Silver," *Phil. Trans.*, Royal Soc., 1885.)

We find that when A, a, x and γ have the same values as in § 59, X = ·699766 dynes per unit current in each coil. This is exceedingly nearly the value found by the series method of § 59.

The student who is interested in the methods of calculation will do well to find the value of M and of $d\,M/dx = d\,M/db$ by the aid of the series $M = G_1 g_1 + G_2 g_2 \ldots$ and of the series $d\,M/db = G_1\,dg_1/db + G_2\,dg_2/db + \ldots$ taking the origin, to which the Gs and gs are referred, at the centre of the small coil. With the same numerical values he will find M = 28·2426 cm. this being the sum of the terms up to and including $G_5 g_5$. Thus the three different methods which we have employed give the same value of M.

Having now explained at considerable length the methods of calculation which must be adopted to determine the value of a current from the forces which are observed to act between the different parts of our apparatus, we shall now go on to consider how Lord Rayleigh put some of the methods into practice.

(To be continued.)

THE WORK OF JOSEPH HENRY.*

If electricity can produce magnetism, may not magnetism produce electricity? Surely this was but a natural question for Henry to ask. Around the middle of the armature of his "quantity magnet" Henry winds a thin copper wire, the ends

* Abstract of Article II. of a series by Miss Mary A. Henry, appearing in the *Electrical Engineer* of New York. For abstract of first article see *The Electrician*, January 29th, p. 327.

Digitized by Google

of which he connects with the coil of a galvanometer forty feet away. He holds the metal plates suspended over the tumbler; the assistant intently watches the distant needle. The plates are dropped into the tumbler; the electric current begins—his magnet is instinct with living power, and it *does* produce electricity in the wire around its armature; for, see—*the needle of the galvanometer swerves.* The question is answered. *Magnetism can produce electricity*, but—most important but—only at the instant of the making and breaking of its galvanic circuit. The gnome has at last been caught at work; the great problem of electrical science is solved.

There is no lack of evidence, as we shall hereafter see, to show that the experiment we have described was actually made in the month of August, 1830.

We have given it as the one by which the problem was solved; but, in fact this was not the first experiment on the part of Henry, which, when properly interpreted, demonstrated the same thing. It was in truth but a logical sequence of results which had been previously obtained. A year earlier, in August, 1829, he was in this very room testing the lifting power of his magnets with different lengths of wire. He had stretched around its bare walls one-fifth of a mile of copper wire, and had made the discovery that by connecting his "intensity magnet" with an "intensity battery," he could make the subtle electric force effective to do mechanical work at any required distance. He had, in fact, made the actual combination which constitutes the electric telegraph of to-day, wherever found and under whatever name. He made his magnet, excited by the intensity battery through that long wire around the room, ring a little bell to announce that the electric telegraph was an accomplished fact. Many times, during the busy years that followed, Henry rang his little bell by means of the electric current, for the edification of the Academy students. He was deeply interested in the experiments which led to this important result, but in the course of them a brilliant and unexpected *spark* had flashed under his eyes from a break in the circuit of a long coiled wire, with which he had united the opposite poles of his battery. In August, 1830, he had taken up the investigation of this new phenomenon, which he called "electrical self-induction in a long helical wire connecting the poles of a galvanic battery."

Many other important results were obtained, which cannot be enumerated here, but the inexorable 1st of September came all too quickly; the academic year of treadmill work; of drilling noisy boys from the rising until the setting of the sun—almost literally, since one of his classes assembled at six in the morning. And so we come down to August, 1831—the August we have dwelt upon so persistently, and very interesting it is now to see what Henry was doing, when Faraday, far away across the sea, is about to enter upon his great work. Spurred to enthusiasm by the brilliant results of the labours of the past year, Henry, to use his own words, is "making preparation for an exhaustive series of experiments upon the identity of electricity and magnetism," and is constructing for the purpose a still larger magnet. But he is not only making this larger magnet, he has constructed a great "reel" wound with a mile of wire. With the magnet we saw him using, and the wire around its armature, he had been able to move a needle forty feet away. What is he doing with this larger magnet and this great reel of a mile of wire? He is making an instrument capable of powerful work. Now look at a modern "dynamo." What is its essential feature? A reel, wound closely with wire, made to revolve within the influence of a great magnet. We do not know in what way Henry intended to revolve his reel within the influence of his magnet; but this does not matter. What he is doing in these August days of 1831 is literally *making a dynamo*, in the modern acceptation of the term. Surely, it was not too much to say that Henry was already almost lost to sight in this particular path in which Faraday is only just about to enter. But the 1st of September came too soon for the completion of his preparations. His room must be given up, as usual, for the ordinary requirements of the Academy.

The great magnet must remain unfinished, and all experiments must cease, not to be resumed until the last two weeks of June, 1832.

Prof. Silliman hears of the new magnet, and writes March 5, 1832, from New Haven to Henry:—

"I have been told that you have constructed a larger galvanic magnet than those of which notices have been published. I write to inquire if there is anything that you would like to have published in the *American Journal* for April, as to any extension or new application of your discovery. I am informed that you have applied it to the separation of fragments of magnetic iron from the mixtures of other things."

And Henry, in his reply of March 28th, 1832, says:—

"In answer to your inquiries as to my further experiments in magnetism, I have little definite to communicate at the present time. I have not entirely abandoned the subject, but have been prevented by circumstances from prosecuting a series of experiments, which were commenced on a very extensive plan. I had partially finished a magnet much larger than any before made, and have constructed a kind of reel on which more than a mile of copper wire was wound. I was obliged to abandon the experiments on account of the room in which my apparatus was erected being wanted for the use of the Academy, and it has not been convenient to me to resume them during the winter."

Other letters tell of the varied occupations of Henry's busy life, which allowed no place for the intensely interesting researches, commenced on so grand a scale and interrupted so inopportunely. They were, as we have said, resumed in the latter part of the following June. What was it that set Henry at work at that time? A paragraph in a periodical, announcing that Faraday, too, had made a great discovery that magnetism could produce electricity. The notice was brief; it showed that electricity in one wire might be made to generate electricity by induction in another wire, and it gave this experiment:—

"In a coil of wire a permanent magnet was inserted, and Faraday found that electricity was produced in the wire when the magnet was inserted in the coil, and when it was withdrawn."

Was this the experiment the one by means of which Faraday made the discovery? We shall see. It should be remembered that this notice conveyed to Henry all the knowledge he had of Faraday's efforts. It impressed upon him the immediate importance of publishing his own results. Although the notice of Faraday's experiment had been published in April, it did not come under Henry's eyes until the following June. He thereupon immediately set to work; repeated the experiments mentioned in the notice, added some others of his own, and hastily prepared a Paper for the July number of *Silliman's Journal*, giving—a fact much to be regretted—only a few of the many interesting and important results he had obtained.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, February 5th.

INSTITUTION OF MECHANICAL ENGINEERS.

7.30 p.m. General Meeting. Papers.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Smoking Concert at St. James's Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Metals at High Temperatures." By Prof. Roberts-Austen, F.R.S.

Cases for binding Volume XXVII., price 2/0; post free, 2/3.

ELECTRICITY SUPPLY MAINS.

The bewildering diversity which at present characterises English central-station practice will not, in all probability, be quite so prominent a feature at the end of the second decade of commercial electrical distribution as it is at the end of the first. The "drehstrom" and Mr. NIKOLA TESLA with his ideal mode of illumination notwithstanding, no fundamentally novel addition has been made within the last five years to the plant at the disposal of our electricity supply companies. Great discoveries, like great events, have a particularly awkward knack of coming to pass at the very moment when they are least expected, when the world at large has come to the complacent conclusion that such-and-such a system is utterly played out, or that such-and-such a science is no longer worthy the attention of serious men, In saying, therefore, that Dr. LODGE'S vision of the boy lighting an entire town by the turning of a handle need not be taken into serious account by anyone when planning a new central station, we do not intend to cast the slightest doubt upon its ultimate realisation, but merely mean to hint that the solution of an equation with everything unknown is not a more difficult problem than to give an entirely novel factor its due importance in everyday work. For all practical

Digitized by Google

purposes, therefore, we may disregard this and all other similar dreams; and, doing so, it is tolerably safe to say that the visible slackening in the tide of fundamental inventions immediately affecting heavy electrical engineering is likely to increase as years go on. Side by side with this there will be a process of elimination, increasing as years go on. At present the Town Councillor in quest of the best system of electric lighting is confronted with examples of distribution by two, three, or five wires; by accumulator, alternate-current, and dynamotor substations; by alternate-current transformers in every house, not to mention the innumerable shades of difference to which the introduction of a variety of ingenious devices gives rise to. We have always sympathised with the unhappy Town Councillor in his hopeless hunt after the ideal; but have been consoled by the knowledge that at the leisurely rate of progress usual with municipal bodies the combatants in this battle of the systems will have become reduced to a minimum by the time the majority of Town Councils begin to make use of their Provisional Orders.

There is, of course, nothing surprising in the fact that so young an art as the distribution of electricity from central stations should exhibit an exuberance of methods. Every new industry is the same in this respect. Indeed, if we remember the widely-different conditions which obtain even in such closely adjacent areas as the City, the West End, and Kensington, not to mention provincial districts, anything like uniformity of practice is out of the question for the time being, if not for all time. In the matter of electric supply mains, on the other hand, it is not quite so easy to understand why electrical engineers should take delight in attacking what is almost identically the same problem all over London in so many different ways. Almost everywhere within the four-mile radius an engineer running his mains is confronted by busy and comparatively narrow streets, a soil of clay, and rubbish perforated with gas, water, telegraph, drain, and other pipes; all of which must be reckoned with, as well as the dislike of the great British public to a little temporary inconvenience and the expense attendant on tearing up roadbeds of wood or asphalt. The problem of how best to take eggs to market is a simple one; but we feel sure that if a hundred unsophisticated minds were concentrated upon it, at least ninety-nine different methods would be devised—all protected by letters patent. As it is with the egg problem, so it is with the carrying of electricity into the consumers' houses; only more so. In the multitude of systems, however, there is doubtless sufficient wisdom to justify the continued existence of perhaps two or three. Meanwhile, pending the evolution of these, the methods now in use are subjected to considerable criticism, disinterested and otherwise. Mr. X.'s culverts, we are told, only escape condemnation because they are laid in a comparatively dry soil; the iron troughs of Mr. Y., we are assured, are rapidly becoming copper-plated; while as to bitumen casing, a block weighing nearly seven pounds can actually be made to take up no less than an ounce or so of water in less than two days. Neither are those who use rubber-covered conductors and iron pipes exempt; the durability of their expensive vulcanised india-rubber cables when exposed to the vicissitudes of an underground London life is liberally discounted; while lead-covered cables in iron piping were, so we were once told, bound either to lose their lead or be coated with iron—we forget which of the two was to happen. The creosoted wood troughing recently introduced in this country is, we are informed, inimical to rubber, and the detractory remarks which the use of glass beads as insulators for electric light cables might well call forth need not be mentioned. In short, in this matter of electric supply mains we are witnessing all the ins and outs of the process by which the fittest proves its right to survive.

The type of main which perhaps commends itself most to the electrical engineer, who is, as all good electrical engineers should be, three-fourths a mechanical engineer, is the so-called "armoured" cable. Given an outer casing of steel or iron to protect from mechanical injury, an inner casing of lead to keep out chemical agents and water, together with plenty of good but inexpensive insulation, we have something which may be fairly expected to meet the exigencies of the situation. Against this type of main it may, indeed, be urged that it is not so well adapted, as some "draw in and out" systems, to cope with a gradually-increasing demand; and that jointing is a somewhat complicated operation. Only two years ago, the extent of the demand for the electric light, and the manner in which it would arise, were completely unknown factors. The same cannot be said now, so that the impossibility of adding to the weight of copper laid down without tearing up the streets is not by any means so serious a defect as it once was. Moreover, a liberal allowance of copper at the start is, from the consumer's point of view, an error on the right side. The jointing of armoured cables requiring some care, it is all the more likely that this work—of the first importance in any system of mains whatsoever—will be allotted to competent men. It will be most interesting to watch the courses adopted by the engineers of various supply companies when fresh districts are taken up, especially when such engineers have shaken themselves free from the contractors who may have promoted the companies. Serious as are the doubts which exist in some minds as to the durability of india-rubber, we believe that as soon as distinct evidence of decay is forthcoming, manufacturers will find a remedy; and every short circuit in a conduit carries with it an important hint for future work, which is not lost sight of. The resources of civilisation are not, therefore, exhausted; and, by the time that the central-station engineer has devised his last device, an electricity supply main will, in all probability, be forthcoming which will, at any rate, fulfil the not too-exacting conditions of metropolitan electric lighting.

REVIEWS.

"**Magnetic Induction in Iron and other Metals.**" By J. A. Ewing, F.R.S. (London: *The Electrician* Printing and Publishing Company, Salisbury-court, Fleet-street.)

Towards the remarkable progress which the science of magnetism has made during the last ten years no single person has contributed in a more conspicuous degree than Prof. Ewing; and no one is more competent than he is to give an adequate account of the results of recent work, so much of which is, indeed, his own. His newly published volume contains little that s to be found in the ordinary text-books. It deals almost ex iclusively with matter which has never before been published in an accessible form, and is only to be found elsewhere either buried in the Transactions of learned societies or scattered through the pages of scientific journals. Out of materials judiciously selected from these sources, and skilfully worked up into a connected and readable shape, the author has constructed a very complete digest of the modern additions to our knowledge regarding magnetic induction.

The subject is regarded throughout from an experimental standpoint, and no mere mathematical discussions, for which this branch of science offers such a tempting field, are indulged in. Such calculations as occur are for the most part of a simple character, requiring nothing more for their comprehension than an elementary knowledge of algebra, though here and there an acquaintance with the notation of the calculus is

Digitized by Google

assumed. No systematic summary of the work can be attempted within the limits assigned to a review, but it may be useful to give an idea of the nature of its contents such as might be derived from a hasty glance through the pages.

In the introductory chapter the principal terms are defined and the fundamental ideas explained, several illustrative examples being given. Here and elsewhere the author attaches no less importance to the notion of intensity of magnetisation, I, than to the notion of magnetic induction, B. "It is not too much to say," he remarks, "that in stating the magnetic qualities of a metal the quantity I is of primary importance. The facts of saturation, the molecular theory and the phenomena of magneto-optics, all demonstrate its physical reality and its fundamental interest." In this opinion everyone whose judgment has not been corrupted by undue familiarity with dynamos will be disposed to concur. A useful feature of the chapter is an elementary discussion of the properties of magnetised ellipsoids.

The second and third chapters treat of measurements of "magnetic quality" by the magnetometric and the ballistic methods respectively. Full practical details are given, as well as a number of valuable hints suggested by the author's experience. In § 48 is an account of Lord Rayleigh's construction for correcting the curve of H and I to allow for the reaction of the specimen on the magnetising field, the rod or wire being regarded as a long ellipsoid. It is shown that even with a specimen the length of which is 400 times its diameter, the effect of the ends is by no means negligible, particularly in that part of the curve where the ascent is steepest. Among other matters of interest the chapters contain descriptions of Ewing's apparatus for demagnetisation by reversals, and of Hopkinson's application of the bar and yoke. Hopkinson's definition of coercive force is also explained.

Chapter IV. contains examples of tests made by the preceding methods. Magnetisation curves are given for various specimens of soft iron, hardened iron, cast iron, steel, nickel, both annealed and hard, and cobalt. The effects of the physical condition of the metal upon its residual magnetism are referred to, and the peculiarities of the different curves are discussed.

Chapter V. is entitled "Magnetic Hysteresis," and deals with a subject which Prof. Ewing has in a special manner made his own. If a specimen of iron, nickel, or cobalt be subjected to a magnetising force which is first raised to a certain value, F, then gradually diminished to zero, then reversed, and brought step by step to – F, then once more reversed, and gradually raised to F again, it is found that the ascending and descending magnetisation curves take two different paths, which generally enclose a space. This peculiarity indicates a tendency on the part of the changes of magnetisation to lag behind the changes of force. The same thing is observed under any cyclic variation of force, unless the range of the variation is very small indeed. "This tendency," we are modestly told, "has received the name of *magnetic hysteresis*, from ὑστερεω—to lag behind," a name which has been universally adopted, and for which, it is hardly necessary to say, the world is indebted to Prof. Ewing himself. A notable effect of hysteresis, to which, among other interesting points, attention is drawn, is that the ratio of B to H, commonly called the permeability, is by no means always the same for the same value of H. It is only under certain limitations that this ratio can be said to have a determinate value. The important practical question of the dissipation of energy through hysteresis is considered, and it is shown that the energy dissipated in a cycle is in each cubic centimetre of the magnetised metal numerically equal to the area, $\int H\,dI$, enclosed by the ascending and descending branches of the magnetisation curve. Several examples are quoted of the dissipation of energy in particular cases; thus, for instance, it appears that the horse-power consumed through hysteresis in a ton of soft iron for 100 cycles per second is 17·7. Then follow some observations as to the influence of speed and of vibration upon hysteresis; and it is incidentally mentioned that a soft-iron wire which was tapped while being magnetised had, at a certain stage, an apparent permeability of no less than 80,000.

Chapter VI. deals with magnetism in very weak fields, mostly ranging from about 0·00004 to 0·04. Within these limits κ and μ are constant, and the magnetisation curves are inclined straight lines. There is also complete absence of retentiveness. A curious phenomenon of weak fields is what the author terms magnetic viscosity, the magnetisation steadily and greatly increasing for a minute or more after the first application of the force.

Chapter VII., relating to magnetism in very strong fields, is one of the most important in the book. In it are described the experiments made by the author and Mr. W. Low, using what they call the "isthmus method," by means of which enormous values of B were reached. The present writer well remembers the half-incredulous astonishment with which the rumour was received in the rooms of the Royal Society that "Ewing had obtained an induction of 45,000 units." To appreciate this statement it must be borne in mind that, according to the opinion (based upon Rowland's researches) which was generally held only a few years ago, it was impossible by any force, however great, to push the induction in iron beyond about 20,000, and that long before this stage was reached κ would have become negative and the iron diamagnetic. The experiments, however, are conclusive, and they show that, while there is apparently no limit to the possible value of B, there is, on the other hand, a very definite limit to I, a result of the greatest theoretical importance. The saturation value of I in wrought iron is about 1,700, and is reached with a force of about 2,000 units, further increase of the force up to 24,500 having no sensible effect. An account is also given of Du Bois' ingenious optical experiments, which fully confirm the author's results; and the chapter ends with a useful table giving corresponding values of H and I for iron, cobalt, and nickel in fields ranging from 100 to 1,200 units.

Chapter VIII., which is concerned with the effects of temperature, is full of valuable matter, but is, perhaps, chiefly interesting for the account which it gives of Hopkinson's remarkable experiments. It concludes with a reference to the question first raised by Faraday—whether any metal whatever might not possibly become magnetic at a sufficiently low temperature.

Chapter IX., on the effects of stress, is a storehouse of curious and paradoxical facts, with which the future framer of a complete molecular theory will have to reckon. Among a host of other matters touched upon is the "Villari reversal," and the relation it bears to the elongations and retractions which rods of the magnetic metals undergo when magnetised.. Reference is made to some extraordinary effects of stress applied *before* magnetisation, but which may, nevertheless, be wiped out by the operation of demagnetisation by reversals; and a summary is given of Nagaoka's experiments on the effects of combined pull and torsion, which culminate in the singular result that the direction of the magnetisation in a nickel wire, which is at the same time pulled and twisted, may, in certain cases, be opposite to the direction of the magnetising force due to the coil surrounding it.

Chapter X., which deals with the conception of the magnetic circuit and some of its applications, will, unlike the last, be of interest chiefly to practical electricians. After a very full and clear treatment of the subject, the author adds this caution: "The student must not think to abandon the consideration of magnetic force and magnetisation at individual points because he finds that the notion of the magnetic circuit is remarkably useful in certain cases, and has in theory no limits to its application. Its real value lies in the fact that by its help problems which would otherwise be intractable may be solved with sufficient exactness for practical purposes." Prof. Ewing makes use of the term "magnetic resistance," to which other high authorities have objected as inappropriate and misleading. He remarks, however, that not only does the "magnetic resistance" depend upon the induction, but for an assigned value of the induction it may have many possible values; we may, indeed, have a magnetic circuit the "resistance" of which is zero, or even negative.

The final chapter begins with a sketch of Weber's well-known molecular theory of magnetism, according to which the molecules of a magnetic metal are themselves magnets, whose axes

Digitized by Google

under ordinary conditions lie in every direction indifferently, but turn into one direction under the influence of a magnetising force. It is pointed out that while this theory harmonises well with many known facts, especially with the lately-established fact that there is a definite saturation value, some difficulty has been experienced in explaining satisfactorily a certain constraint to which the molecules must necessarily be subjected in order that saturation may not be produced by the smallest magnetising force. Weber himself supposed that each molecule was acted upon by a force tending to keep it in its original direction. Maxwell made the further assumption that, unless the magnetic force was small, the molecule, after deflection, was affected by a kind of permanent set, not quite returning to its original position when the force ceased to act. Others, again, have supposed the constraint to be of a frictional nature. After discussing these hypotheses, and indicating how they fail to accord with observed phenomena, Prof. Ewing shows that the constraint may, without any arbitrary assumptions whatever, be simply and completely accounted for by the mutual action which the molecules exert upon one another in their character of magnets. This view is amply supported both by reasoning and experiment. At p. 338 there is given a very perfect magnetisation curve, obtained in an experiment by the magnetometric method, in which instead of a bar of iron a group of 24 little pivoted magnets was employed. The three stages of the magnetising process are quite well defined; and those who have seen a similar model at the meeting of the British Association or the Royal Institution will remember how effectively it reproduces other phenomena of magnetic induction. There can be little doubt that Prof. Ewing has arrived at the true solution of a problem which has exercised the ingenuity of so many eminent magneticians. After reference to a number of experiments bearing upon the molecular theory, the chapter closes with a short account of Ampère's hypothesis of magnetic molecules.

Full of novel and important matter, the book is written, with admirable clearness, in a pleasant and easy style. It abounds with references to original memoirs for the benefit of those who may wish to pursue the subject further; and in the form of tables and curves it contains a wealth of data which cannot fail to be of value in the application of the science. It is not too much to say that no student of physics and no practical electrician can afford to be without a copy.

SHELFORD BIDWELL.

INSTITUTION OF ELECTRICAL ENGINEERS.

PRESIDENTIAL ADDRESS OF PROFESSOR W. E. AYRTON, F.R.S.

Electrotechnics.

(Continued from page 326.)

But my colleagues and I view with considerable apprehension the way in which the present wide demands for teachers in technical schools is being supplied. Several of our own students, for example, tempted by the comparatively high remuneration that is offered, have become teachers in technical schools immediately on leaving the Central Institution. In many respects they are undoubtedly well qualified; but if they had first spent some time in Works before attempting to teach technical subjects they would have better understood the wants of the persons whom they have undertaken to instruct.

No greater mistake can be made than to think that a student who has distinguished himself at a technical college can dispense with the training of the factory, unless it be the opposite mistake of imagining that the factory training is equivalent to, or even something better than, that given at a modern school of engineering.

It is the province of the manufacturer to turn out apparatus and machinery as cheaply, quickly, and as well made as possible; it is the province of the technical teacher to prepare the human tool for subsequent grinding and polishing in the factory.

And this necessity for the teacher having himself passed through the shops has especial weight when we are dealing with the technical instruction of workmen, for in such a case there are three requirements absolutely necessary—first, knowing how to teach; secondly, possessing a fair knowledge of scientific principles; and thirdly—and this is perhaps the most important of all—knowing exactly what it is that the workman ought to learn in order to help him in his particular trade.

Schoolmasters may have the first two requisites, and so may do valuable work in connection with the variety teaching at a Polytechnic; but they are not in touch with the workshop, and, therefore, no matter what may be their scholastic attainments, no matter what the extent of their experience in teaching the young, they are not the persons to give the real technical education to workmen.

In addition, then, to the polytechnics we must have special schools for special industries, where workmen are taught the application of science to their special trades; and everything taught in such a school must be taught as bearing on the particular industry which the school is intended to benefit. A teacher of physics, for instance, must remember that he is not training physicists, but workmen whose use of physical principles will be bounded by their application to their special trade; for the great danger of such teachers is that, carried away with enthusiasm for their own subject, they will not subordinate it properly to the end in view—viz., helping the workman to know what will be useful to him in his work.

Indeed, as Prof. Huxley pointed out in his original report to the Livery Companies Committee, "Success in any form of practical life is not an affair of mere knowledge. Even in the learned profession knowledge *per se* is of less consequence than people are apt to suppose. . . A system of technical education may be arranged so as to help the scholar to use his intelligence to acquire a fair store of elementary knowledge, which shall be thorough as far as it goes, and to learn to employ his hands, while leaving him fresh, vigorous, and content, and such a system will render an invaluable service to all those who come under its influence.

"But if, on the other hand, education tends to the encouragement of bookishness, if it sets the goal of youthful ambition, not in knowing, but in being able to pass an examination, especially if it fosters the delusion that brain work is, in itself, a nobler or more respectable kind of occupation than handiwork, and leads to the sacrifice of health and strength in the pursuit of mere learning, then such a system may do incalculable harm, and lead to the rapid ruin of the industries it is intended to serve."

And I venture to think that not merely at technical schools for workmen, but at technical colleges for engineers, it should be ever remembered that the main object of the training is not the cultivation of mental gymnastics, but to enable the student to acquire knowledge and habits which shall be professionally useful to him in after life.

"Useful learning usefully taught" would be no bad motto for technical institutions, seeing that those who favour the compulsory teaching of Greek are apparently willing to accept the converse as the motto for the University. For example, Mr. Butcher, in his address delivered at the end of last Session, at University College, Bangor, said:—"We may claim it as a distinction that in the seats of academic learning little or nothing useful is taught;" and in an article in last month's "Fortnightly Review," congratulating Cambridge on its recent victory over the *barbarian*, Mr Bury says quite candidly, "Greek is useless; but its uselessness is the very strongest reason for its being a compulsory subject in the University course." And he adds in italics, "*for the true function of a University is the teaching of useless learning.*"

A few of the County Councils have realised that the real teaching of the application of science to a special industry, which is what the British workman is so much in need of, cannot be given, as well as host of other subjects, out of limited funds. For example, Bedfordshire has decided to spend its grant of £4,343 mainly in agriculture, market gardening, the straw trade, domestic economy, and industries for women; Cambridgeshire and Cheshire devote themselves largely to the teaching of agricultural pursuits.

Digitized by Google

But other places aim at issuing vast comprehensive programmes and turning out yearly a mighty army of students, knowing it may be the something of everything, but who certainly will not know the everything of something. For example, the Holland division of Lincolnshire has decided out of only £2,000 a year to make grants for dairy schools, university extension and art schools, agricultural science, domestic economy, mechanics, commercial subjects, and ambulance teaching; while Bootle, with a yearly expenditure of only the same amount, maintains classes in five commercial subjects, in 16 science and art subjects, in cookery, wood working tools, as well as four courses of university extension lectures.

Because a certain building in Regent-street famed for its ghost and its diving bell was years ago named "the Polytechnic," the majority of the new technical institutions which are being established in London at such vast cost are also called "Polytechnics," and will, I fear, give only an English polytechnic course. Now such recreative education, although admirable for those who seek relief from work in the use of their minds, is not generally sufficient for those of your workmen who use their minds in their daily occupation.

It ought, then, to be thoroughly recognised that there is an entirely new problem to be solved, and that the solution of this problem, in so far as it has been worked out at the Finsbury College, and at other places giving practical teaching in the evening, must, in the language of the mathematician, be regarded simply as "the singular solution," and not the general solution of the problem of technically educating the British workman.

Let us gratefully accept the English polytechnics, for they will undoubtedly confer benefit on our country; and all credit be to those who have so generously established them. But do not let us be misled by the similarity between their generic name and that of the German "polytechnicum" into fancying that the recreative courses of the one are equivalent to the serious education given by the other.

Like Oliver Twist, let us ask for more; for on behalf of the large number of minds already employed in the electrical industry, and on behalf of the still larger number that will in the future be so employed, it is our duty to secure that ample provision be made in this country for the practical teaching of electrotechnics on a scale comparable with that afforded in the Technical High Schools of Germany and the Institutes of Technology of the United States.

On the screen you see projected a photograph of the façade of the Technical High School at Charlottenburg (Berlin), which appears extensive and grand; and yet, as you will see from the next photograph, it was only a small portion of the whole building that you were looking at in the first photograph. This is but one of the many technical high schools in different towns of Germany, and yet *it covers an area more than five times as large as that occupied by the Central Technical Institution in Exhibition-road, London, cost four times as much to erect, and has more than four times as much spent on its yearly maintenance.*

The next photograph shows a building devoted wholly to the training of electrical engineers, being that of the Electrotechnical Institution Montefiore, at Liége, which Prof. Gerard kindly took me over this last summer, and which has since been opened. When I tell you that there are rooms for small direct-current dynamos, separate rooms for large direct-current dynamos, separate rooms for alternators, and that every three students have a separate little laboratory with the necessary measuring instruments all to themselves, your educational mouths will water as mine did.

We now cross the Atlantic to the Massachusetts Institute of Technology, Boston, which, as you see, consists of several distinct buildings, the centre one being that which contains the electrical laboratories. The dynamo room now seen on the screen has many small and large dynamos in it, and yet there is ample room to walk about; for this dynamo room occupies a space many times as large as that devoted to dynamos at the Central Technical Institution of London.

Prof. Cross was so good as to mention in a letter that was shown me some two years ago that several of the devices that had been worked out for the electrical laboratories of the City and Guilds Institute had been reproduced at Massachusetts; but there is one device that Prof. Cross has succeeded in working out, and which I should be most glad to see copied by the City and Guilds Institute, and that is, having one assistant for every five students working in the physical laboratories.

Franklin Hall, presided over by Prof. Nichols, is devoted solely to the department of pure and applied physics at the Cornell University, Ithaca. You see how large this four-storied building must be, for look how small the four-wheeled waggon standing in front of it appears.

The next three photographs show some of the provisions made for teaching electrotechnics in Franklin Hall, the electrical laboratory under Prof. Moler, and the dynamo room under Prof. Ryan, whose analyses of alternate-current curves are well known to you all.

I might show you photographs of the electrical laboratories in Prof. Weber's new building for physics at Zurich, on which £100,000 has been already expended. In fact, my choice of magnificent Continental and American laboratories has been so great that I have hardly known which to select as specimens.

But there is one thing I cannot show you—and it must remain for the exercise of your influence as representatives of the electrical profession to make that possible—the British electrotechnical laboratories for education and research, which are truly worthy of London, the capital of the world.

The training of such students as those at the Central Institution must, of course, differ essentially from that of the electrical artisan, not because we, or the students, expect that on entering a factory at the conclusion of their college course they will start, as a rule, much above the bottom of the ladder, but because they hope in time to be able to mount higher.

They are, therefore, taught not merely to construct meters and motors, use dynamos and engines, build a chimney and lay a street main, but, as they are not to spend all their lives wiring houses or watching a central station voltmeter, they are well practised in calculating and designing, and they further obtain sufficient acquaintanee with the methods of attacking new problems not to be daunted when they meet with them in after life.

But so strong is becoming our belief in the value of science to the manufacturer, so anti-classical are some of us growing, that there is great risk that the literary side of the education of an electrical engineer will soon be wholly neglected. Now, important as it no doubt is for him to be quite at home with electrical apparatus and machinery, it is no less important, if he is to take advantage quickly of the progress made abroad, that he should be able to read a German or a French newspaper. I do not merely mean that with a grammar and dictionary and plenty of leisure he should be able to translate the newspaper sentence by sentence, like a scholar preparing to morrow's lesson, but that he should have the power to glance down the columns, gather the gist of the articles, and quickly see whether there be anything new that especially concerns him.

How many electricians are there in this country who can, for example, take up the *Zeitschrift für Instrumentenkunde*, or the *Electrotechnische Zeitschrift*, and look through their pages as they do those of *The Electrician*, the *Electrical Review*, or of the *Electrical Engineer* during breakfast on Friday morning? There are, I know, a few—I wish I were one of them.

And yet examples are not wanting of the scientific isolation that is caused by not possessing that familiarity with foreign languages which is such a characteristic of diplomatists and hotel waiters. Take, for instance, the fact that whereas manganin was manufactured on a commercial scale in Germany, and German resistance coils have for the last three years been constructed of this material with a temperature coefficient of nearly zero, the very existence of this alloy was unknown to the majority of English instrument makers a few weeks ago; and even now many of them are still unacquainted with the composition of manganin, and its peculiar properties, as well as with the results of the extensive and striking experiments that have been carried out at the Reichsanstalt at Charlottenburg on the temperature coefficient and specific resistance of all sorts of manganese-copper-zinc-nickel-iron alloys.

This Physikalisch-Technischen Reichsanstalt, I may mention, is an establishment totally distinct from the Technical High

Digitized by Google

School in Charlottenburg, some photographs of which I showed you this evening. The Reichsanstalt is not an institution with students, but a vast series of Imperial laboratories, presided over by Prof. von Helmholtz, solely used for carrying out researches in pure and technical physics. The investigations are conducted under the direction of Dr. Loewenherz, aided by 46 assistants.

We have no establishment in Great Britain at all comparable with this Reichsanstalt. The original work turned out there in electrotechnics alone is considerable. Here are some of the published accounts of researches immediately bearing on your profession, which Dr. St. Lindeck has been so kind to send me: "Hardening Steel Magnets," "Standard Resistance Coils for Large Currents," "Tests of Commercial Ammeters and Voltmeters," "Mercury Standard Resistance," "Photometric Investigations," "Compensation Apparatus for use in Potential Difference Measurements," "Alloys for Resistance Coils," and so on.

Surely it is part of the technical education of the electrical engineer to be taught how to read such pamphlets as these with comparative ease.

A working knowledge of French and German can be obtained without the necessity of learning to express oneself fluently in epigrammatic French, or to imitate with facility the word building of a native German; and with such a working knowledge the average technical student may rest content. But as regards his own language he should aim at something higher, and therefore the electrical engineering students of our own country should be, I would urge, practised in writing—yes, and also speaking—vigorous English.

Only the other day Prof. Nichols, of the Cornell University, was deploring with me the rarity of finding a student of electrotechnics who could write a decent report. The experimental methods employed in the student's investigation might have been good, the mathematical analysis suitable, and the calculations exact; but the description of the apparatus and of the results obtained would be scattered pell-mell over the paper as if the writer were quite ignorant of the fact that the style in which a dish is served up is nearly as important as the goodness of its ingredients.

Why do you suppose that Huxley's portrait has nearly as much prominence given it in the photographer's window as that of a duke or a ballet-dancer? Quite as much because he knows how to express himself in terse and forcible English as on account of his wide scientific knowledge; because, even when writing about dry bones, the flow of his language clothes them with rounded forms.

But you will ask, how are we to find the time for all this linguistic and literary polish? Has the electrical student of to-day so many spare hours that fresh subjects of study must be sought for to fill up his leisure moments?

At present much time has to be wasted at technical and other colleges teaching students 16 years or older elementary mathematics and science which ought to have been mastered before that age. When the education of childhood is improved, when the higher education of women is properly carried out, there will be no need for male experts to trouble about general training, for then children will spend less time at school and learn more; boys and girls will, as a matter of course, acquire the foundation of modern languages and general education; and students at a college will be able to devote their whole time to the special training—scientific, manual, linguistic, and literary—which pertains to the particular profession which their special tastes will generally lead them to select before the age of 16.

And just as methods of teaching applied science have been developed during the past few years, so I look forward to the growth of new methods of teaching what may be called applied literature. For it seems to me that there is a want of breadth in the view that because the study of Greek verse would be unprofitable for a student of electrotechnics, and because he has neither the taste nor the time to enter into the intricacies of etymology and grammar, therefore the study of modern languages and literature, even as directly applied to his profession, should form no part of his regular training.

As well might it be thought (and I am sorry to say this view is not yet quite exploded) that because a student has neither the taste nor the time for the study of abstract mathematics, therefore he should be debarred from all work in a physical laboratory. Well, if it be generally accepted that although a young electrical engineer has no chance of becoming a Cayley or a Maxwell, still he ought to be taught such portions of mathematics and physics as will be directly useful to him in his profession, why should the certainty that he will neither become a Jebb nor a Dickens lead us to tolerate an inability on his part to speak fluently and write tersely his own language, surpassed only by his entire ignorance of every other?

Habits of scientific thought are highly necessary for electrical students; to be masters of their own language, and to know something of one or two others I venture to think are no less so; but the main result to be achieved, the main object to be aimed at with every system of education, is moral thoroughness.

For until every workman, foreman, engineer, and manufacturer feels regret and pain at seeing work inefficiently performed our national system of education will be incomplete.

All the labour now expended in watching work in progress, and in testing it when completed to see that it has not been scamped, is so much withdrawn from the real business of production. Every rise, therefore, in the standard of thoroughness of a community means the saving of waste labour. But far greater than this will be the actual increase in the productive power when each gives his best endeavours to his share of the world's work. And greatest of all will be the gain in the nation's happiness, since he who works with his whole soul knows no drudgery.

The lesson to be taught is no new one—it was set many centuries ago; and hundreds of thousands a year will indeed be well spent if the County Councils can so succeed in bringing home to the hearts of us all this—"Whatsoever thy hand findeth to do, do it with thy might."

ON THE STRUCTURE OF A SOLID DIELECTRIC, AND THE RESIDUAL CHARGE.

BY W. A. PRICE.

The form of dielectric on whose insulating properties the most careful experiments have been made is that of the gutta-percha covering of the conducting wires used for submarine cables; and the following discussion applies principally to what occurs in the ordinary practice of testing the cores of such cables immersed in water by the method of direct deflection. In this method of testing the poles of a battery, usually of considerable E.M.F., is connected to the inside and outside conducting coatings of the dielectric; these are the conductor of the cable, and the water in which it is immersed. The currents of electricity which pass from the battery to the surfaces of the dielectric are measured on a galvanometer placed in the circuit. These currents are ordinarily recognised as divisible into two parts; one is the current which serves to charge the cable considered as a condenser, and, while at first of considerable magnitude, is appreciable only for a very short time after the battery key is closed; the other is a current which is considered to flow from one conducting surface to the other through the dielectric considered as a conductor.

After applying the battery the following events occur:—

i. A considerable quantity of electricity, which we may call the condenser charge, accumulates within a short time on each of the two conducting surfaces—+ electricity on one, − electricity on the other, the quantities being equal and very soon reaching their maximum values.

ii. The considerable flow of electricity from the battery ceases as soon as the condenser charges have accumulated, and then is observed a steady current of small quantity which appears to flow from one pole of the battery to the other through the dielectric.

iii. This small steady current regularly diminishes, at first rapidly, then more and more slowly, and finally, after a considerable lapse of time, attains a value from which no further change takes place.

Digitized by Google

iv. On removing the battery and connecting the two conducting surfaces with a wire, the condenser charges of electricity accumulated on the conducting surfaces combine rapidly through the wire.

v. Then is observed passing through the connecting wire a small steady current of electricity in the opposite direction to the original charging current. This is called in cable-testing rooms the earth-current. It diminishes at first rapidly, then more and more slowly, and finally reaches a zero value, when the dielectric appears to be in the same condition as before the battery was originally applied.

Let us suppose the dielectric to contain a number of parts of molecular dimensions which possess always electrical polarity similar to crystals, *i.e.*, are + electrified at one end and − at the other; we suppose this electrification to be permanent and indestructible except by decomposition of the substance, and

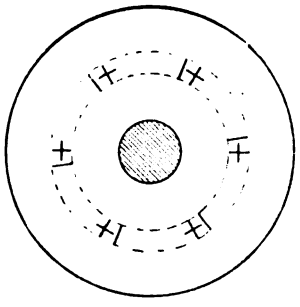

FIG. 1.—Section of cable, showing electrified parts arranged so that the lines of electric displacement form closed curves in the dielectric, giving no external evidence of electrification.

that the electrified parts are set in a viscous medium which may be a conductor of electricity as in gutta-percha, or an insulator as in glass.

From the same considerations as those which in Ewing's speculation and experiments on the structure of a magnet explain the tendency of soft iron to show no external magnetic field, it will be seen that in such a system the lines of electric displacement will tend to form closed curves of small dimensions in the substance of the dielectric, and the whole system will exhibit no external electrification (see Fig. 1), the electrified parts lying in all sorts of directions.

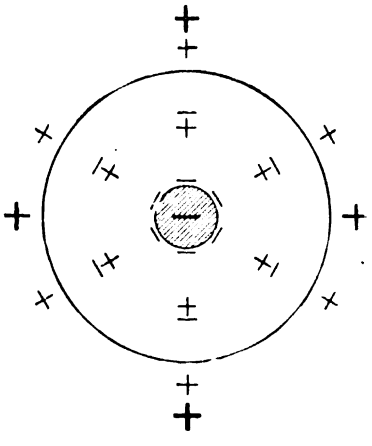

FIG. 2.—Section of cable when the electrified parts are turned by the action of the condenser charges, and induce, in virtue of their own polarity, further charges on the conducting surfaces. The thick signs represent the condenser charges.

On the application of the + and − capacity charges to the two surfaces of the dielectric, all these parts will immediately tend to set in one direction, so as to present their + charged ends to the − charged surface, and their − charged ends to the + charged one.

As each element turns in this way fresh + and − charges from the battery will accumulate on the conducting surfaces equal in amount to the charges on the faces of the terminals pre sented to them.

The elements, moreover, being in a viscous medium, will turn slowly and gradually. On this supposition, on the first application of the battery, the current, besides supplying the condenser charges, also provides the extra charges gradually accumulating on the conducting surfaces to meet the charges on the electrified elements as they gradually turn into their final positions (see Fig. 2). It may be argued from the analogous case of the magnetisation of soft iron that these additional charges will be demanded rapidly at first and more slowly afterwards, thus explaining the gradual decrease of the current. Ultimately, when the whole are turned parallel to one another and perpendicular to the charged surfaces, the dielectric is completely "electrified" (I use the term of the cable engineer), and no further action takes place. The current which continues to flow from the battery passes through the gutta-percha as a conductor. If glass is the dielectric, as in a Leyden jar, the current ceases altogether.

The earth current observed after the battery is removed is due to the gradual swinging back of the electrified elements to their old positions, or to new ones which satisfy the condition of forming closed curves in the dielectric for the lines of displacement, and thereby setting free the induced charges on the conducting surfaces.

We may notice that only with a battery of very high potential will the electrified elements be really set parallel to one another, since their positions will be determined by the resultant couple of the actions on them of the condenser charges and of the other elements in their neighbourhood.

What I have termed complete electrification is exactly analogous to the saturation of a magnet, and if it were found after the cessation of the earth current that the surfaces of the dielectric still bore charges of electricity, the existence of a property analogous to hysteresis would be established. The very slow rate at which "electrification" of a cable takes place may be compared to the "viscous hysteresis" observed by Ewing in iron.

Also we may note that on this hypothesis the dielectric resistance of a cable should be determined from the minimum value of the galvanometer deflection after the electrification is complete, and not from the deflection observed at some arbitrary interval of time after the application of the battery.

This hypothesis, then, rests on the supposition that "electrification" is due, not to any production of polarisation by expenditure of battery power, but to a direction of polarised elements already in existence. A supposition of this kind forms the bases of the at present accepted ideas on the nature both of electrolysis and magnetism.

MOTORS WITH REVOLVING FIELDS.*

BY W. RECHNIEWSKI.

By means of a revolving field it is possible to build two kinds of motors, differing largely both as to principle and performance—

1. *The Synchronous Motor with Revolving Field.*—This motor closely resembles any ordinary synchronous alternating motor. A "Brown" three-phase generator constitutes such a motor. In this motor there is a relatively powerful electro-magnet, generally with several poles, which is movable about a shaft, and which is surrounded by the revolving field. We can see easily that if such an electro-magnet turns synchronously with the field it will be carried by the latter exactly as if, in place of currents of different phases, there were an ordinary alternating current.

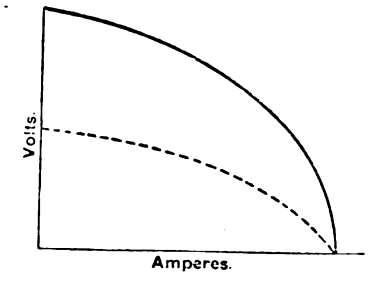
2. *Motors with Revolving Fields properly so called.*—In this class of motor there is no electro-magnet excited by a continuous external current; there is simply a rotating field and an armature wound with different circuits, in which the revolving field produces currents by induction; between these induced currents and the inducing currents of the revolving field reactions are produced, tending to move the armature

* From *L'Electricien, Revue Internationale de l'Electricité.* January 2, 1892.

Digitized by Google

in the direction of the rotation of the field. These currents can only be produced by a difference of speed between the rotating armature and the rotating field; these motors are, therefore, necessarily non-synchronous.

The two kinds of motors are distinguished further by other properties—for instance, by that of self-induction, as will appear later on. It is possible to combine them and to construct a motor which, at the moment of starting, is actuated by the induced currents, and which, when the speed of synchronism is obtained, continues to run as a synchronous motor. I have endeavoured in the present article to make as clear as possible the reactions which take place in these motors, so as to be in a position to estimate the advantages and disadvantages of each kind of construction, to calculate the torque produced at each instant, and to see also what kind of winding is preferable on the armature in order to obtain the best results with the least possible expense. Some very simple considerations, as we shall see, give all these results without calculation, by a series of simple reasonings, and I will first consider motors with revolving fields properly so called, *i.e.*, those in which the armature is formed of circuits closed upon themselves, or upon some resistance, and traversed only by the currents induced by the revolving field. When we seek to describe the different reactions which take place in a revolving field motor—to express, for instance, the torque as a function of the speed and resistance, or of the self-induction introduced into the armature circuit—we meet with very considerable difficulties. By the method which I shall describe I take into account all the facts with sufficient exactitude, while entirely avoiding difficult formulæ or calculations. This method, which consists in comparing revolving field motors with alternating machines, allows us to apply all that we know about the latter to the study of the phenomena which occur in the former.



In a revolving-field motor there are magnetic poles of constant strength (or, at least, we endeavour to make them so) which revolve with a definite speed around an armature, which they cause to rotate with them. This armature has a certain number of closed circuits, the rotation of the revolving fields induces currents in these circuits, and it is the reaction between these currents and the movable poles of the field-magnets which produces the torque. Considering the torque only, things happen exactly as if the poles of the field-magnets were fixed, and the armature only revolved inside it with a speed ω equal to the difference between the speed of the revolving field and the revolving armature (relative speed of the armature with reference to the revolving field). Under these conditions we should have an ordinary alternating current machine revolving at the speed ω, and, as we know sufficiently well the properties of an ordinary alternating current machine, we could calculate the value of the torque in every case which might arise in practice. The torque C is equal to the total work T produced in the armature ÷ by 2π times the speed of rotation,

$$C = \frac{T}{2\pi\omega} \text{ where } \omega = \text{the speed of rotation.}$$

The work T comprises both the work produced in the windings of the armature by induction ($\int ei\,dt$) and the work lost by hysteresis; the torque C for a given speed ω will vary directly with the work T; the current can be varied by changing the resistance put in the armature circuit. But we know that the work T does not increase indefinitely when we diminish this resistance, the characteristic of an alternating current machine having a form represented by the curve shown above, and which implies that a maximum of work is given by a particular value, I, of the current, and consequently of the external resistance. The maximum torque will be obtained with this definite, easily-determined armature current. Consequently, in a revolving field motor of which the armature turns at the speed $V - \omega$, we must introduce a resistance, easily determined, in the circuit of the armature, to obtain the maximum torque of which the motor is capable when revolving at the speed $V - \omega$. We see, then, that the maximum value of the torque is the same for all armature speeds, and that it occurs when the current circulating in it has the same value, I. To obtain this value, I, we must change the resistance introduced into the armature circuit for different speeds. Let us consider the curve. If the armature turns at half speed the ordinates of the curve will be diminished one-half, so also the work T; but the maximum work will occur for the same value of the current I. We have then $T' \max = T \max/2$, but, the speed being one-half, we have the same torque.

Now let us see what takes place when a revolving field motor starts. At this moment the slip of the armature ω, *i.e.*, the difference between the speed of the armature and that of the rotating field, is a maximum. To get a powerful torque, we must have a large production of work in the armature, this work being spent partly in the armature itself, and partly in the external circuit or resistance. In order that the torque may be comparable to the normal torque of an alternating machine at full load, the work absorbed in the armature circuit must be the same; this shows the importance of a resistance at starting. If we keep the resistance constant, the work absorbed by the armature will diminish as the square of the relative speed ω; this work is proportional to $\int \frac{e^2}{R}$, where e varies proportionally with ω. The torque varying as ω, it will become much weaker at high speeds, and it will be necessary to decrease the resistance so as to keep I constant, all the resistance being finally cut out. The armature will then revolve nearly synchronously, hysteresis will be negligible, and the entire work produced in the armature will be spent in heating the windings. The work may be relatively very little, but, the difference of speed ω between the armature and the revolving field being also very small, the torque may be very effective.

We have seen that the torque is always equal to $\frac{T}{2\pi\omega}$. For an ordinary armature, the efficiency of which is 95 per cent., about 20 per cent. of the work T will be spent in the armature at the moment of starting, and the remainder in the external resistance. We could try to build a machine with very powerful electro-magnets and a very small armature, so as to diminish the reactions of the armature and avoid by this means the use of external resistance. In fact, if the reaction of the armature were nil and its resistance constant, the work T would increase as the square of the relative speed ω, and consequently the motor couple would be a maximum at the moment of starting. We do not, however, believe this is practicable for the following reasons:—

1. Because very powerful electro-magnets with much iron would be required, which implies a great loss by hysteresis.

2. The large number of turns which would have to be put upon the electro-magnets would very much increase their self-induction, and by that alone would diminish the useful effect of the high voltages which we can use with this system.

3. In order to produce at starting a torque equal to the normal torque at full speed, it is necessary that the energy spent in heating the armature at the moment of starting should be 20 times greater than the heat spent during normal work; and if, for example, the start was made rather slowly, or an unforeseen stop occurred, there would be danger of burning up the armature.

4. At starting, the field current would have to be very large (with a difference of phase from that of the armature); and there is a risk, not only of burning the fusible cut-outs if there be such in the circuit, but of causing variations in the lamps placed in the neighbourhood of the motors. In fact, to produce the same torque at starting, when resistance is not employed, a current is required in the armature four or five times stronger

Digitized by Google

Under these conditions, the current in the field circuit increases nearly in the same proportion, and the loss by heating in the field is comparable to that in the armature. The efficiency of the motor would, therefore, be very low at starting. Self-induction in the circuit of the armature is not only no advantage, but is prejudicial according to my view; in fact, whatever be the speed of the armature, self-induction tends to diminish the work T actually absorbed by the armature and transformed into heat, and consequently to lessen the torque, which is proportional to T. We must see clearly here that the torque is not only proportional to the armature current I, which can be made more or less constant by means of self-induction, but depends also on the difference of phase between the armature and field-magnet currents. The torque, in a word, is proportional to the total work T created in the armature by the revolving field. The work T in all practical cases will be spent heating the armature and the rheostat; but it might be very easily transformed into mechanical work by another motor.

I may here make an interesting remark with reference to the work done by the field-magnet currents. Whatever be the speed of the armature, so long as the torque remains constant, by keeping the armature current I invariable by means of a rheostat, the work spent in the field circuit is constant. At the moment of starting the work is entirely spent in heating the field windings, the armature, and the resistance, and as the armature speed increases a larger proportion of this work is transformed into mechanical work, capable of utilisation on the armature shaft; but the sum of the mechanical work on the shaft and that transformed into heat on the armature is constant so long as the torque is constant. We see, then, that these motors only lend themselves to those purposes at which they will work almost always at one speed; at every other speed the efficiency will be very low.

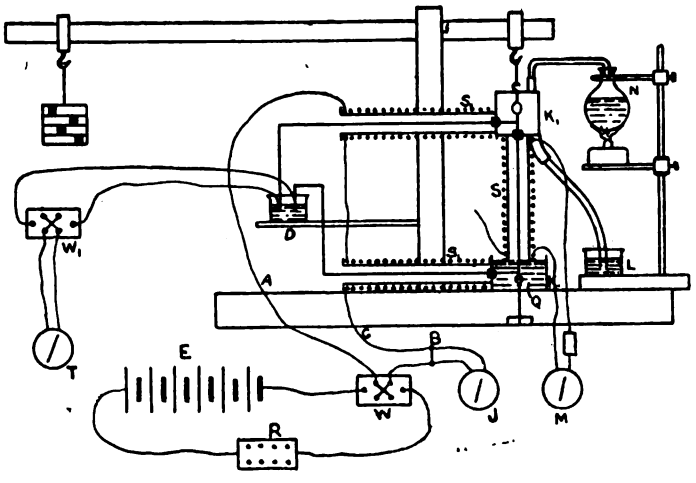
This method of considering the phenomena of revolving-field motors, and comparing them with alternating machines, is very convenient, because it tells us the best method of winding the armature so as to have maximum useful effect for a given current. The rules are the same as for the armatures of alternating-current machines. If the armature has teeth or radial projections, its rotation may become entirely synchronous with that of the field. At that moment the currents will cease to circulate in the windings of the armature, since there is no longer any difference of speed between the armature and the field, and the rotation will be maintained in a rather different manner; then the poles formed upon the teeth of the armature are attracted by the poles of the revolving field; at this moment hysteresis in the armature is strictly *nil*.

The self-induction of revolving-field motors is considerable; the changes of magnetism in each field coil are, in fact, quite comparable to those which are produced in the winding of the armature of an alternating machine of the same power.

To sum up: the advantage of the revolving-field motor over that of a synchronous alternating-current motor, such as is understood by an ordinary alternating-current generator, consists in this—that it is self-starting, and that it is not necessary to bring first the armature up to the speed of sychronism by independent means. On the other hand, it has this grave defect—the self-induction of the field magnets diminishes the useful effects of high voltages. To avoid this inconvenience we can use condensers. In synchronous motors, on the other hand, by making the magnets relatively powerful, we reduce the self-induction of the armature as low as we please. If then we desire to transmit large powers to a considerable distance, the use of ordinary alternators would appear to be preferable. The case is different if we wish to distribute electrical energy to a number of small motors made as simply as possible. The synchronous motor can be made with a revolving field, as we have already seen. We can, in fact, wind two circuits on the armature; one of these will act exactly as in the revolving-field motors already considered, and will move the armature in the direction of the revolving field; through the other circuit we can pass a constant continuous current which would produce fixed poles upon the armatures. With this arrangement the speed will increase to synchronism, as soon as that is attained; the first circuit will no longer be traversed by any current, the fixed poles of the armature will be directly moved by the revolving poles of the field and no longer by the intervention of the induced currents. If the fixed poles of the armature are very powerful, the field current will not have any influence upon their strength, so that the self-induction of the field will be *nil*, and the total voltage may be utilised for the production of mechanical work. It is evident that in practice it will be impossible to make the self-induction of the field circuits *nil*; but in all cases we can diminish it largely by using synchronous motors with powerful electro-magnets, and can also utilise the greatest part of the voltage employed, and consequently reduce the section of conductors which carry the current to almost the theoretical minimum corresponding to the voltage used. This synchronous motor with revolving field, of which the moveable part constitutes a powerful electro-magnet, will then be self-starting (with a small load, it is true), and run at full speed with very little self-induction. It will combine, therefore, the conditions of the two systems, but retain the inconvenience of a low efficiency at all the intermediate speeds between that of rest and the speed of synchronism. A two or three-phase generator can be used as a synchronous motor.

MAGNETO-THERMO-ELECTRIC EXPERIMENTS.*

It has long been known that the magnetisation of an iron or nickel wire modifies its thermo-electric properties. This fact, pointed out for the first time by Sir William Thomson,† was ascertained by forming a thermo-electric couple of two iron bars, one of which was magnetised and one of which was not. The current flowed in a different manner according as the magnetisation was transversal or longitudinal. In the former case the current flowed from the magnetised bar to the non-magnetised bar; in the latter case its direction was the reverse. Petruschewki, in 1874, and again later, in 1881, Strouhal and Barrus, repeated Thomson's experiments and confirmed the general results. The current generated, was, however, too weak for it to be possible to establish any relation between it and the intensity of magnetisation. Recently, M. Bachmetjew reinvestigated the whole question, making use of extremely sensitive measuring apparatus; notably, a Rosenthal galvanometer made by Edelmann, which enabled him to extend his researches to parallel questions, such as the influence of compression and tension on thermo-electric properties. The experimental arrangement employed by M. Bachmetjew recalls the one previously used by him,‡ the new apparatus being, however, of wood.



The metallic wire to be tested was suspended within the spiral S (*see* Fig.), 350mm. long, which was of ·8mm. wire, wound so as to give 225 turns. The *iron* wire was bent into a ring at P and Q. Above P and Q copper conductors were soldered. The end P was in a little closed brass box, insulated from the iron wire by means of an india-rubber stopper. Two other iron wires were placed horizontally at P and Q, and surrounded by solenoids S_1 S_1, similar to S. The ends of the horizontal wires terminated in a vessel, D, filled with cold water (t=10deg.). Copper conductors

soldered to these iron wires led to the Rosenthal galvanometer T, passing through the switch W_1. The far end of the lower horizontal wire was also plunged into a vessel of water at 10deg. The upper muffle K, which was perfectly hermetic, was in communication on the one hand with a vessel of water heated to 100deg., and on the other with a refrigerator, L, which allowed the steam from N to condense. The magnetising current was obtained from a large bichromate six-cell battery, E, the circuit being through the rheostat R, the switch W, the wire A, the two horizontal spirals $S_1 S_1$, and then by the wire C through a small Wiedemann galvanometer, J, back to the battery. As the current was a very large one, the galvanometer was shunted at B.

The general mode of experimenting was as follows. After having allowed the vapour of water to circulate for ten minutes in K the switch W_1 was closed ; when a thermo-electric current, due doubtless to residual magnetism, was manifested. A current which was kept reversing was then passed until the opening of the circuit no longer affected the observed deflection on the galvanometer T. The circuit was then closed several times (four) in succession, the deflection being carefully observed. The value of the magnetising current was indicated by the galvanometer J, and the value of the induction current by the galvanometer M.

M. Bachmetjew, experimenting in this manner, and varying the conditions of the problem, obtained a series of numerical data, arranged in different tables, from which it follows that the thermo-electric current increases with the magnetising force, and this proportionally to the magnetising current, but somewhat slower than the square of the vanished magnetism (*magnétisme disparu*).

The iron wire employed was 1·6mm. in diameter, the temperature of the two joints being 10deg. and 97deg. The nickel wire (diameter = 1mm. ; temperature 10deg. and 97deg.) did not appear to give the same results as the iron wire ; the thermo-electric current undoubtedly increased with the magnetising current, but it was about twice as small as in the case of the iron wire, all other things being equal.

In the case of compressed and stretched wires the following conclusions were arrived at. With a constant magnetising current the thermo-electric current undergoes a notable diminution on stretching a magnetised wire, and it was possible to predict that it would be zero for a certain weight, which was confirmed by experiment. The influence of compression is not less curious. M. Bachmetjew has ascertained in fact that the thermo-electric current produced by the magnetisation of an iron wire under compression diminishes with the magnetisation when the magnetising forces are weak, whilst it increases when the magnetising forces are strong. In the case of nickel it was observed that the more the metal was compressed the weaker the thermo-electric currents, whatever the values of the magnetising forces employed.

The primary cause of these various phenomena could not be determined *à priori*. On examining them several questions naturally arise. Can magnetisation by itself produce a modification in the molecular condition of a body, and also change its thermo-electric properties ? In other words, does the molecular structure of a body vary according as the molecular magnets occupy such and such a relative position ? The results described above have enabled M. Bachmetjew to build up a theory solving this interesting problem.*

If magnetism is the sole cause of these variations in thermo-electric property, they ought to persist as long as the magnetisation. Experiment shows that this is not always so. For instance, when an iron wire is stretched and magnetised, the influence of the magnetisation on its thermo-electric properties is much weaker than when the wire is not stretched ; this influence may become zero for a certain tension, whilst its magnetic permeability increases with tension. It follows from this that the influence of magnetisation on the thermo-electric properties of iron is only a secondary influence. We must go back to a primary cause of a markedly permanent character, such, for instance, as magnetic elongation. If the variation of the length of the iron wire is the cause of the variation of its thermo-electric properties, magnetisation will be ineffectual when the conditions of the experiment are such as to preclude elongation. Now, M. Bachmetjew has proved the following thesis:—When an iron wire gives out a sound, *i.e.*, varies its length, under the influence of an intermittent magnetisation, its thermo-electric properties are influenced by the magnetisation ; but as soon as the sound, *i.e.*, the variation of length, diminishes (owing to tension, for instance) the influence of the magnetisation also diminishes, and becomes zero when the iron can no longer produce a sound, *i.e.*, no longer varies in length, under the influence of the intermittent current. From this we may conclude that the action of the magnetisation is purely secondary ; *i.e.*, that its action depends on the variation of length, *i.e.*, on the variation in the distance between the molecular magnets, and not upon their relative position. Be the molecular magnets arranged parallel or perpendicularly to the longitudinal axis of the bar, the result is the same. It follows, therefore, that the molecular magnets possess the same dimensions in all directions, contrary to Tyndall's hypothesis, which considered the molecular magnets to be longer in the direction of their magnetic axes,

M. Bachmetjew's results may be summed up as follows :—

(1) The thermo-electric force of an element formed of a bar of iron (similarly with nickel) longitudinally magnetised, and a second non-magnetised bar increases a little slower than the square of the vanished magnetism (*magnétisme disparu*).

(2) It is directly proportional to the magnetising force.

(3) It depends also upon the longitudinal mechanical tension of the magnetic wire in the following manner :—The greater the tension, the weaker is the influence of magnetisation on the thermo-electric properties of iron and nickel. In the case of iron the influence becomes zero when the metal is submitted to a certain tension. If the pull is increased the influence may even become negative ; that is to say, the thermo-electric current is reversed.

(4) Magnetisation has no effect on the electromotive force of a couple formed of stretched and unstretched iron wire, when the stretched wire no longer changes its length under the influence of the magnetisation.

(5) Compression has a certain effect on magneto-thermo-electric phenomena. It diminishes the thermo-electric force in the case of nickel, and increases it in the case of iron. When the magnetisation is very weak, compression has a weakening effect in both instances.

(6) The direction of longitudinal magnetisation has no influence on the direction of the thermo-electric current in a couple consisting of non-magnetised longitudinally magnetised iron.

(7) The thermo-electric current flows from the longitudinally magnetised to the non-magnetised metal, when it contracts under the influence of magnetisation.

(8) *Ceteris paribus*, thermo-electric properties are more strongly modified by magnetisation in the case of iron than in the case of nickel.

(9) The thermo-electric current flows from the non-magnetised to the longitudinally magnetised metal (which is contrary to what Thomson found for nickel).

(10) Magnetism does not *per se* modify the thermo-electric properties of iron and nickel, but only does so indirectly owing to the linear elongation which it produces.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES, F.R.S.

Before dealing with the subjects set down on the programme for that evening's lecture, Prof. Forbes said he wished once more to express the strong feeling he had of the great desirability of electrical engineers not slurring over the difficulties which lay in their way in regard to a cheap distribution of electricity from central stations. There were two sources of expense, viz., the cost of generation and the cost of distribution : the latter defect would cure itself as soon as the demand for current became more general ; the former could only be mitigated by careful attention to central-station details. Few people even yet realised the waste which ensued from running engines on light loads, and in heating up large batteries of boilers for a few hours' work. The employment of suitable engines and appropriate units would do much to reduce the cost of generation. The kernel of the whole matter was the "load factor," a term first used by Mr. Crompton in his Paper read last year before the Institution of Civil Engineers, and which he had defined in no less than five different ways. He (Prof. Forbes) would venture to clarify ideas by the three following definitions :—

$$\text{Machinery Load Factor for any period} = \frac{\text{Average current during that period}}{\text{Maximum current obtainable from machinery}};$$

$$\text{Current Load Factor for any period} = \frac{\text{Average current during that period}}{\text{Maximum current ever supplied from station}};$$

$$\text{Temporary Load Factor for any period} = \frac{\text{Average current during that period}}{\text{Maximum current supplied during period}}.$$

One of the first attempts at a high-pressure supply was that by means of storage batteries at Colchester, where groups of accumulators were charged in series and discharged in parallel. The scheme was not a success, the storage batteries not being reliable. An exactly similar scheme was now being tried in Chelsea. The system was a satisfactory one in many ways, the only serious objection being its cost.

Another idea of the early days of electric lighting was the multiple-series system. The five-wire system used in the Secteur Clichy at Paris was yet another way of distributing continuous currents at high pressure without allowing an unduly high pressure within the houses. The difficulty of the five-wire system, viz., the

* Abstract of Cantor Lecture II., 2, delivered before the Society of Arts, February 1, 1892.

Digitized by Google

balancing of the circuits, had been overcome in an ingenious manner. Automatic switching of the lamps from one circuit to another was out of the question; so a "compensator," in the shape of four dynamos on the same shaft, was employed, each machine being connected to one of the four circuits. If any particular circuit received too much pressure, then the pressure on that dynamo was greater than that on the other machines, and it acted as a motor and drove them faster, raising the pressure. This device, although ingenious, was not quite satisfactory, and was going to be abandoned. All four machines required to be continually at work, and some 12 H.P. was wasted all day long in each compensator; as an alternative, batteries of accumulators might be placed across the mains.

The alternate-current transformer system was, however, the high-pressure system of distribution *par excellence*. Its convenience was enormous. The alternate-current transformer gave us the utmost facility by a most beautiful device for using high pressure without any fear of it entering the consumers' wires. The alternate-current transformer system also lent itself to accurate distribution—a point not sufficiently attended to in the past. Either by "regulating transformers" or "choking coils" at the central station we were able to regulate the pressure of our feeders to a nicety.

The alternate-current transformer had been the object of much interested criticism. It was, however, subject to certain disadvantages. The first defect was that hitherto the alternate current had not been available for driving motors. This was not so serious a drawback as it looked at first sight. Experience of places where motors had been put on to the lighting circuits was not altogether favourable to this arrangement. In many central stations indeed it had been found desirable to have different circuits for motors. The chief idea in seeking to get motors on to lighting circuits was originally to improve the load factor, but it had been found that the demand for power and light inconveniently overlapped. A second defect of alternate currents was the fact that they were not easily made available for electro-chemical work or the charging of storage batteries.

Considerable changes might be expected in our present method of distributing alternate currents. The custom of putting transformers into the consumers' houses was very costly, and rendered regulation difficult. A system of transformer sub-stations feeding into a low-pressure network was the coming thing. There was not the slightest doubt that the substations could be made perfectly self-regulating, so that the transformers might be placed in underground vaults. The gains from this method would be a diminution of the hysteresis losses and of the idle current. We might safely look for an average efficiency of 90 per cent. in our substation transformers. The feeling in favour of substations was so general amongst engineers that we might look to its universal adoption in the immediate future.

Were we working on right lines in the matter of "frequency"? He thought a radical alteration might be expected in this matter. The pioneers of alternate currents, seeing that it would be costly to place transformers of large dimensions in the consumers' houses, employed high frequencies. The result was a very considerable waste of energy by hysteresis. Now that we were all going to use substations and large transforming units, the frequencies of 130 and 80 might well be brought down to 5 or 10, *i.e.*, those in our continuous-current armatures. There were several other advantages attached to a low frequency. With the large secondary mains that we should require with the substation system, the "skin effect" would be very pronounced with our present frequencies, If we reduced our alternations it became possible to employ continuous-current motors (having well laminated field-magnets) on our alternate-current circuits. With the frequencies at present in vogue, an ordinary 100-volt motor would require another 100 volts to drive the current through the field magnets. Reduce the frequency to 5, and only 6 volts extra were required. Motors of this character were being introduced on alternate-current circuits in America, Alternate-current motors were, however, being developed in quite another direction. Nevertheless, even then high frequencies would be no gain. A low frequency would enable us by means of commutators to make alternate currents available for electro-chemical and other similar purposes. It was most desirable that at the present moment, when we were considering the question of substations and low-pressure networks, to also carefully consider the question of reducing our frequencies.

Another high-pressure system was that known as the continuous-current transformer system. In this, high-pressure currents were usually generated at a distant centre and transmitted to dynamotor substations. Owing to the armature reactions of a dynamotor or continuous-current transformer being nearly equal and opposite, the efficiency of this apparatus was extremely high. We should consider the fact that in working in this manner we are only employing the high electrical pressure as a means of transmitting energy, and that there were other means of so doing. These were the compressed air and hydraulic systems. A combination of compressed air and electricity was used in Paris by M. Popp. It was not altogether economical, but deserved more attention than had hitherto been paid to it. London afforded an example of a hydraulic supply. Here, also, the large size of pipe required was a drawback when it came to running the mains through crowded streets. A 6in. pipe, with the water at 1,700ft. pressure, could only transmit 100 H.P.

Another mode of distribution was by means of gas, special or ordinary. He (Prof. Forbes) had no hesitation in saying that in a very large number of cases it would be economical to use gas-engine substations. Gas-engines had not hitherto been made large, merely because they had not been wanted. There were, however, at present engines of 170 H.P. at work. Gas-engines were compact and economical (16 cubic feet of gas per I.H.P. per hour), and required no wasteful boilers.

Prof. Forbes concluded his lecture by a rapid glance at some of the various systems of mains in use. The insulators employed were vulcanised india-rubber, okonite, various bituminous compounds, and air. Some employed lead-covered cables, others left their conductors bare. A few years ago he had drawn attention to some most serious defects which had occurred in the lead-covered cables in Berlin and Rome, due to want of experience in manufacture and want of care in laying. Great improvements had, however, been made since then. At the Manchester (1887) meeting of the British Association he had described a system which he still thought possessed many advantages. He then proposed to use cast-iron pipes, and to run bare copper *tubes* through them, supported at intervals by porcelain blocks. At first the copper tubes alone might be used as conductors, but as the demand increased larger and larger conductors might be drawn through them. In making house connections the inner conductors need never be touched, connection being made with the outer tubes only.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *January* 22, 1892.

New Western Union Office at New York.—On Wednesday last the press were invited to examine the new operating rooms of the Western Union Telegraph Company, taking the place of those destroyed by fire some months ago. The process of repair involving the practical rebuilding of the top of the Western Union building, very many improvements have been made, and the accommodation is far better than it has ever been before. The general operating rooms are on the seventh and eighth floors, each of them 75 feet wide by 200 feet long, having windows on every side. The eighth story contains the main operating room for the great bulk of the commercial business, while the floor below is devoted to special instruments of every kind, gold and stock reporters, Wheatstone transmitters, special quadruplex lines, and the like. Something like 1,200 operators are employed on these two floors. A new arrangement of switchboards has been adopted as facilitating the shifting of instruments from circuit to circuit, and the distribution of the business through the operating rooms. An automatic carrier service enables the messages to be distributed to the various operating tables from a central gallery, ann in general the arrangements for the rapid transaction of business are far better than in the old days. The fire has been a positive benefit so far as efficiency is concerned.

The Law of Hysteresis.—On Tuesday last was held the regular monthly meeting of the American Institute of Electrical Engineers, at which the principal Paper was on the Law of Hysteresis, by Mr. Steinmetz. Last summer the author conducted a long series of experiments on hysteresis under different circumstances, using, for the most part, the alternating current. The Paper was an exceedingly elaborate one, and was followed by a protracted discussion. The most useful part of it was a collection of various results in tabular form, giving a considerable array of facts regarding hysteresis that otherwise would be somewhat difficult to find.

The Electric Traction Question at Brooklyn.—The Mayor of Brooklyn has been looking into the working of the trolley system in other cities, and has found, possibly to his surprise and disappointment, that the general sentiment from the cities with which he has communicated is very strongly in favour of

Digitized by Google

electric traction, even by the trolley system; and, in fact, adverse evidence is almost non-existent, all the protests against the trolley coming from people who are totally ignorant of its practical operation, and who would never ride in electric cars were they introduced. It is the same story that has been told of every city that has proposed such a change. The great bulk of the people universally desire it, the protests coming from a few sore-headed property owners, who ride in their own carriages and would prefer to see their fellow-citizens walk. The Mayor will probably take formal action on the resolution last passed by the Board of Aldermen this week. It is generally supposed that he will sign it, but in case of a veto the ordinance will probably be passed over his head.

SCANDINAVIAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

COPENHAGEN, *January* 30, 1892.

The electric light will be used in Christiania for the lighting of one or two of its principal streets, as soon as the central station is completed. The public electric lighting will comprise Carl Johan-street, two or three squares, and probably portions of the quay. This will necessitate about 40 arc lamps and those of about 1,000 c.p. will be adopted. It is proposed to have them at a height of 30ft. above the street, and with an interval of 200ft. The electric light will be from four to ten times more powerful than the present gas light. It is not without interest to compare the various tenders received for the Christiania central electric station, the difference between the respective offers being very considerable. The tenders were as follows:—

	Aggregate Tender.	Revised Tender.
Edison General Company	£53,290	£55,235
Crompton and Co.	47,486	45,764
Siemens Bros. and Co.	45,310	43,184
Electric Construction Corporation	34,068	44,670
Siemens and Halske	39,221	41,250
Schuckert and Co.	38,180	38,180
Thomson-Houston Electric Company	40,778	40,931
Actiengesellschaft Helios	43,113	41,391
Compagnie Continentale Edison	44,095	44,095
Kummer & Co.	32,625	32,625
Sharp and Kent	45,284	43,160
Woodhouse and Rawson United	40,580	38,454
Actiengesellschaft für Chromaccumulatoren	35,311	40,006

The above tenders were for the entire installation. On the same day as the contract with Schuckert and Co. was signed, Siemens and Halske offered to reduce their tender by £3,750, which was thought slightly out of order, as the tenders were then known, and no notice was, under the circumstances, taken of the offer. It attracted some attention that the tender from Kummer and Co., which was some £5,555 lower than Schuckert and Co.'s, was not accepted; but it was thought advisable to accept the offer from a firm which had already completed several large central station installations in preference to one from a firm which has, as yet, no experience of this kind. The cables were in both cases specified to be from Felten and Guilleaume.

Several smaller towns in Scandinavia are also going in for central electric stations. Among these is Bergen in Norway, where the installation will comprise the lighting of the principal thoroughfares, of the whole of the harbour, and of private houses. At Helsingborg in Sweden the electric central station was opened in December, the work having been very promptly carried out by the contractors, Siemens and Halske. The cable system has a length of 7½ miles, and is calculated for about 1,000 lamps. In Sorö, Denmark, it has also been decided to construct a small central electric station.

Electric bleaching was introduced in the course of last year at the Uddehalen chemical wood pulp manufactory. To begin with, only two batteries were used; but the result was so satisfactory that sufficient batteries were installed to treat the whole present output of bleached wood pulp, and electric bleaching is now the only method used at the works. A turbine works the 45 H.P. dynamo, as well as the circulating pumps and other machinery. There are now five batteries. This installation is the first of its kind in Scandinavia.

The completion of the Copenhagen electric central station has been somewhat delayed by wintry weather; but it is confidently expected that it will be able to commence operations about the middle of February. The number of customers has exceeded all expectation.

CORRESPONDENCE.

THE DETERMINATION OF THE CAPACITY OF LONG SUBMARINE CABLES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In taking the capacity of cables by Gott's method there appears another way of arriving at the same result, without, as with, the correction put forward by Mr. Dearlove in his interesting Paper to *The Electrician* of March 6th last, if *the insulation resistance of the condenser and cable is equalised in the inverse ratio of their respective capacities.*

Taking the case, in the table below, of the cable having 280 mf., and condenser of 99 mf.,—an insulation test of each was first taken, and they gave 0·63 and 10 megohms respectively after 10 seconds charge. The condenser, to have its proper ratio of I R, had, therefore, to be reduced to 1·78 megohms by shunting. $\left(\frac{280 \times 0{\cdot}63}{99} = 1{\cdot}78\Omega.\right)$

This being done, and the slide ratio adjusted to 1000/2830, a perfectly dead-beat balance was obtained at the galvanometer, and the discharge at the junction of cable and condenser was *nil*; consequently, no correction was required, and the chance of error in reading d and d' in Dearlove's formula was avoided.

Then $1000\omega : 2800\omega :: 99$ mf. : 280·17 = capacity of the cable.

The shunt across the condenser should be adjustable, so that it can be altered in conjunction with the slide ratio to obtain the double balance.

Under precisely the same conditions (except that the condensers were not shunted), and applying Dearlove's correction, a result of 280·10 mf. was obtained.

Cable.		Standard condensers mf.	When balanced at galvanometer & dis. *nil*.		Result in mf.	By Dearlove's method.
Length in knots.	Insulation resistance.		Slide ratio.	Reduced I R of condensers.		
	Ω			Ω		
154·5	0·36	39·696	1010/1199	0·431	47·12	47·13 mf.
331·8	0·25*	59·448	1010/1660	0·414	97·70	97·33 mf.
910·6	0·63	99·000	1000/2830	1·78	280·17	280·10 mf.

* Reduced by artificial leak at home end from 2·5.

With regard to the cable of 97 mf. there is a discrepancy of 0·37 mf. between the two methods, but, considering the I R of the cable was artificially reduced by a leak at the home end from 2·5 to 0·25 megohm, the discrepancy is surprisingly small, and is due, apparently, to the fact that the increased leakage was concentrated at one point, instead of being spread over the whole cable. The result of the test of the 47 mf. cable, which has a naturally low I R, would seem to confirm this.

This double-zero method might with advantage be used as a test for localising a break in a cable where the end offers a rather high resistance, such as would occur if the G P were drawn over the conductor.—Yours, &c., F. W.

Alexandria, Egypt.

GRAPHICS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: Prof. Thompson has in his letter laid down the true value of graphic methods: but will you allow me to protest against his treatment of my old friend Geometrical Conics? Having formerly taught Geometrical Conics in a public school, I have formed a very high opinion of its value as an *educational* subject. Some of the pleasantest hours I have ever spent in teaching have been to large classes on this subject. The interest of the boys is at once awakened after their dreary Trigonometry, and they begin to think that after all mathematics was not invented by a clique of Bedlamites. After a three weeks' course of Geometrical Conics, they are quite fresh and eager to attack Analytical Conics and the Calculus.

In the excellent treatise of Cockshott and Walters, and there are many others, the proofs are certainly not "long winded," and the theorems cannot always be disposed of by a "couple

Digitized by Google

of lines of the calculus." I could give a good many theorems in which analysis comes off a bad second. A knowledge of Newton's "Principia," or of Geometrical Conics, may not be of much service to the technical electrical student, but this is no valid reason why the study of them should be banished from our public schools and universities.—Yours, &c.,

Faraday House, Jan. 30, 1892. ALEXANDER RUSSELL.

[Without wishing to raise the the question of "usefulness" of an educational subject, we must point out that in our leading article of January 27th we discussed graphics for directly utilitarian purposes for the every-day work of the man of science, but more especially for the engineer. Professor Silvanus Thompson's energetic letter last week treated the subject mainly with reference to the engineering student. "Geometrical conics," as a greased pole, may afford capital exercise in mathemetical gymnastics, and may, as Mr. Russell thinks, have a high educational value—but that is rather outside our province.—ED. *E.*]

HARMONIC ANALYSIS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I was prevented from setting the following exercise to a special class which has now disbanded. The members read your paper. May I ask you to act as a medium of communication? As many others of your readers may wish to work examples in harmonic analysis I will give the simple instructions. Professor Henrici has invented a simple machine to do the work. I have taught my students how to work on squared paper, but Bottomley's book of tables will enable the work to be done sufficiently accurately.

There is a periodic function, the value of which, at every twenty-fourth part of the whole periodic time, is as follows :—

Time.	F.	Time.	F.
0	13·3660	12	3·3660
1	14·0355	13	6·9645
2	14·3300	14	5·6700
3	14·3295	15	4·6705
4	14·1340	16	4·1330
5	13·8295	17	4·1705
6	13·4640	18	4·8030
7	13·0355	19	5·9645
8	12·5000	20	7·5000
9	11·7940	21	9·3940
10	10·8660	22	10·8660
11	9·7060	23	12·2940

If T is the whole periodic time, let k stand for $2\pi/T$. Then $F = A_0 + A_1 \sin kt + B_1 \cos kt + A_2 \sin 2kt + B_2 \cos 2kt +$ &c. We have to find the values of A_0, A_1, B_1, A_2, B_2, &c. Having found them, we may write F in the shape $F = A_0 + M_1 \sin(kt + e_1) + M_2 \sin(2kt + e_2) +$, &c. If $M_1 = \sqrt{A_1^2 + B_1^2}$ and $\tan e_1 = B_1/A_1$; and so for the other amplitudes and epochs.

I.	II.	III.	IV.	V.	VI.	VII.
Time.	F	kt in deg.	Sin kt.	F × sin kt.	Cos kt.	F × cos kt.
0	13·3660	0	0	0	1·0	13·3660
1	14·0355	15	·2588	3·6324	0·9659	13·5559
2	14·3300	30	·5000	7·1650	0·8660	12·4098
3	14·3295	45	·7071	10·1324	0·7071	10·1324
4	14·1340	60	·8660	12·2400	0·5000	7·0670
...	...	...	...	...	...	...

I.	VIII.	IX.	X.	XI.
Time.	Sin 2kt.	F × sin 2kt.	Cos 2kt.	F × cos 2kt.
0	0	0	1·0000	13·3660
1	·5000	7·0177	·8660	12·1543
2	·8660	12·4078	·5000	7·1650
3	1·0000	14·3295	0	0
4	·8660	12·2400	-·5000	-7·0670
...	...	...	...	...

Rule.

Write down the values of time and F in columns I. and II. Write down kt in degrees (the last value being 345°, since 0° is the same as 360°). Write in column IV. the values of sin kt, taking care of the + and − signs. Column V. is troublesome, because each number is the product of the numbers in II. and IV. The meanings of the other columns are as stated.

Now A_0 is the mean value of all the 24 numbers in Column II.
A_1 is *twice* the mean value of all the 24 numbers in Column V.
B_1 is *twice* the mean value of all the 24 numbers in Column VII.
A_2 is *twice* the mean value of all the 24 numbers in Column IX.
B_2 is *twice* the mean value of all the 24 numbers in Column XI.

If higher harmonics than the octave are sought for, we must multiply F by sin 3kt and cos 3kt, sin 4kt and cos 4kt, &c. The work is not so very tedious as one might expect.

One of my students, Mr. Cachmaille, makes out F to be $F = 9{\cdot}966 + 5{\cdot}039 \sin(kt + 29°{\cdot}9) - 1{\cdot}053 \sin(2kt - 55°{\cdot}3)$.

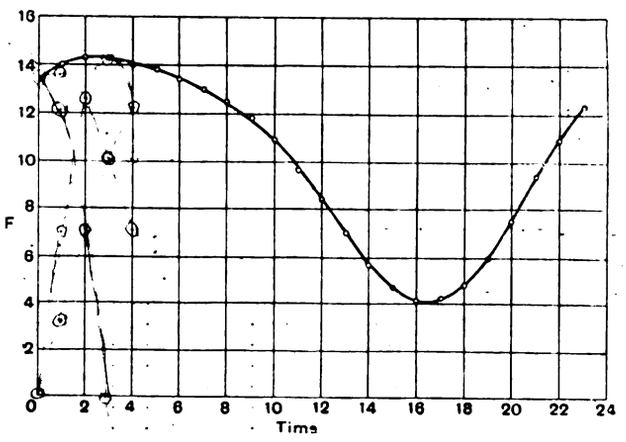
He may have made some mistakes, I do not know; but I certainly arranged that F should turn out to be

$$F = 10 + 5 \sin(kt + 30°) - \sin(2kt - 60°).$$

What I intended is not so important, however, as the true answer.—Yours, &c., JOHN PERRY.

Finsbury Technical College, Jan. 29, 1892.

[Prof. Perry's letter comes very opportunely after Dr. Fleming's article upon Harmonic Analysis of Transformer Curves; andthough the work seems rather arduous, it is extremely simple and little else than mere arithmetic. In order that our readers may appreciate the problem, we have plotted the curve alluded to from the table upon which the calculation is based.—ED. *E.*]



ELECTRIC TRACTION AND THE LIVERPOOL TRAMWAYS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: With reference to your paragraph in last week's issue on page 317, headed "Electric Traction and the Liverpool Tramways," two errors have crept into the Chairman's remarks of the meeting of shareholders of the Liverpool United Omnibus and Tramway Company. The first is that this Company, who offered to supply electric traction to the Liverpool Tramway Company, offered the Glasgow Corporation to run their cars at 3½d. per mile by electric traction; and the second is that a comparison is drawn between 7d. per car mile for the operation of 12 cars, the number required by the Liverpool Company, and 3½d. for 100 cars, the number intended to be operated electrically by the Glasgow Corporation. The inference is drawn that the difference between the two sums is accounted for by the physical difficulties of the Liverpool streets; but 100 cars can be operated electrically for a great deal less than 7d. per car mile; and 234, the number now operated by the Liverpool Tramway Company by horses, could undoubtedly be operated for at least a saving of 1d. a mile on their present horse traction.

I think it is only fair to electric traction, and to my Company, who made the offer referred to in the paragraph, that the facts should be clearly stated; and, as we have always received the greatest kindness from the Chairman and Directors of the Liverpool United Tramways Company, we feel sure that it was not their intention to make a statement that would be misleading.—Yours, &c.,

THE GENERAL ELECTRIC POWER AND TRACTION CO. (LD.).
London, E.C., February 3, 1892. THOS. SMITH, Secretary.

TRADE NOTES AND NOTICES.

[Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

On Monday next, February 8th, will be issued the tenth annual edition of the above well-known annual, price 7s. 6d.; post free, in the United Kingdom, 8s 3d.; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements relating to Central Stations, Electric Railways and Tramways, &c., have been made complete; the tables giving useful data relating to dynamos, alternators, motors, transformers, batteries, &c, have been remodelled and amplified, with the object of giving fuller particulars than hitherto relating to the principal makes of dynamos and other electrical machinery and plant. A new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns; no labour or expense has been spared to make this information complete, and we believe that this new feature will be found of great service to electrical firms having business dealings with the companies referred to. The information given respecting the Local Authorities of Great Britain has been perfected and is thoroughly reliable. An important feature of the book is the space devoted to the officials of Foreign and Colonial Governments who have the superintendence of contracts and the giving of orders for electrical plant and apparatus; and as this has been kindly supplied by the various Government departments, it can be relied upon, as can also the particulars given respecting the Home Government departments.

As our readers are aware, the DIRECTORY is due at the end of January, and, as a matter of fact, is kept posted up to within two or three days of the date of publication, as is evidenced by the inclusion of several new firms and changes of address which have only taken place at the extreme end of January, 1892.

The profession will find "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

TENDERS RECEIVED.—The following tenders have been received by the Bournemouth Town Council for lighting the pier, pleasure grounds, and new municipal offices with electric light. No tender has yet been accepted:—

Barclay and Son	£6,302	7	6
Ronald Scott and Co.	5,810	0	0
Mather and Platt	5,280	0	0
	4,690	0	0
Berry, Harrison, and Co.	4,947	0	0
Goddard, Massey, and Warner	4,840	0	0
Roper's Electrical Engineering Company (Limited)	4,627	0	0
Siemens Bros. and Co. (Limited)	4,439	0	0
Laing, Wharton, and Down	4,310	16	8
Brush Electrical Engineering Company (Limited).	4,038	0	0
Woodhouse and Rawson United (Limited)	3,800	0	0
Crompton and Co. (Limited)	3,340	9	6
Johnson and Phillips	2,878	13	0
Rashleigh Phipps and Dawson	2,870	0	0
Paterson and Cooper	2,617	0	0
Fowler, Lancaster, and Co. (Limited)	2,644	0	0
	2,334	0	0
Manchester Edison-Swan Company (Limited)	1,898	0	0
J. D. F. Andrews and Co.	1,433	0	0

CHICAGO EXHIBITION, 1893.—Intending exhibitors are reminded by announcement in our advertisement columns that the 29th inst. is the date fixed for the receipt of applications for space, and that after that date applications can only be received subject to space being available.

HYDRAULIC LEAD MACHINERY.—We have received from Messrs. J. and W. Weems, Perseverance Iron Works, Johnstone, Scotland, circulars and price lists of block tin-lined lead pipe. Various hydraulic pipe presses, lead-rolling mills, and patent machinery for covering telegraph, telephone, and electric light cables, with lead sheaths, are referred to. The leading cable-making firms appear to have been supplied with lead-working machinery by this firm.

MESSRS. J. SUNDERLAND AND CO. (HALIFAX).—We have received a new price list from this firm, who are making dynamos under the Statter-Brunton, and other patents. They also supply Statter voltmeters and ammeters, medical induction coils, and other sundries. We have tried one of their medical coils, costing only a few shillings, and find that with a single cell of the General Electric Company's dry batteries, the current is more than we can stand, with dry hands.

MESSRS. PATERSON AND COOPER.—This firm have just issued Sections E and F of their illustrated catalogue. Section E is devoted to the illustration and description of electric globes, shades, reflectors, &c., and full particulars are given respecting a large variety of Messrs. Paterson and Cooper's stock of these articles. The illustrations are clearly printed in colours, and a large number of all kinds of globes and shades are shown, many of the designs being exceedingly effective. This section concludes with some more illustrations of externally cut and internally frosted ship globes, as well as a number of registered designs, both clear and frosted. Section F deals with silk and paper shades, and contains particulars of a number of very pretty designs.

MESSRS. CANNINGTON, SHAW AND CO.—This well-known firm, of Sherdley Glass Works, St. Helen's, announce that their partnership having expired by effluxion of time, they have decided to register their business under the Limited Liability Act, and have transferred it to a private limited company, which will pay and receive all debts owing by or to the old firm. This step has been taken in order to facilitate new arrangements and to admit some of their juniors. The whole of the capital will be taken up by the existing partners and their nominees.

INDIA-RUBBER ESTATES COMPANY (LIMITED) (IN LIQUIDATION).—Notice is given that a second dividend, of 2s. 6d., is payable at the liquidator's, 7, New-court, Lincoln's Inn, on any day except Saturday.

CALENDARS FOR 1892.—We have received from Messrs. Woodhouse and Rawson United (Limited) a movable calendar for 1892.

——— The General Electric Power and Traction Company (Limited) are issuing a neat hanging calendar for 1892, with illustrations.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C. from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

January 9, 1892.

487. R. E. B. CROMPTON. London. Improvements in means or apparatus for producing decorative, advertising or other effects by the aid of electricity.

491. C. A. W. HULTMAN. London. Improvements in and relating to underground conduits for electric wires.

495. G. H. ROBERTSON. London. An improved electric battery electrolyte.

499. F. M. NEWTON and T. HAWKINS. London. A new or improved dynamotor or continuous current transformer, and method of winding the field magnets of such.

January 11, 1892.

548. E. P. ALLAM. London. Improvements in holders for incandescent electric lamps.

January 12, 1892.

568. G. BUMBERG. Southend-on-Sea. Improvements in electric incandescent lamps.

576. H. D. FITZPATRICK. Glasgow. A new or improved automatic electric heat alarm. (The Electric Heat Alarm Company, United States.)

638. P. RABBIDGE. London. Improvements in telephonic switching appliances.

645. P. GENDRON. London. Improvements relating to electric welding.

January 13, 1892.

650. R. KENNEDY. Glasgow. Improvements in methods of operating alternating-current electro-motors, and in apparatus therefor.

January 14, 1892.

772. J. C. SWANNE. London. Electric shade holder.

785. E. E. RIES. Baltimore, W. S. A. Improvements in regulating sockets or fixtures for incandescent electric lamps and other translating devices, and in methods of regulating the flow of current to such lamps and other devices. [Date applied for under Patents Act, 1883, Sec. 103, July 6, 1891, being date of application in the United States.]

791. J. B. HAMOND. London. Improvements in laying and insulating electrical wires.

Digitized by Google

798. Siemens Bros., and Co (Limited). London. Improvements in electrical conductors. (Messrs. Siemens and Halske, Germany.)

January 15, 1892.

825. W. Fairweather. Glasgow. Improvements in electric cables. (E. F. Phillips, United States.)

837. H. Hunter. Leith. Improvements in fixed or moveable electrical switch for incandescent lamps.

843. T. Coad. London. Improvements in and connected with mounting incandescent lamps for safety purposes, particularly applicable to electric miners' safety lamps.

871. H. H. Lake. London. Improvements in electric cables. (D. Brooks, junior, United States.)

875. R. J. Rae. Walthamstow. Improvements in electric lighting, and for other like purposes.

January 16, 1892.

925. A. Marr. Manchester. Improvements in telephonic receivers.

936. S. Schuckert and A. Wacker. London. An electro mechanical device for producing corresponding positions in transmitting and receiving apparatus.

January 25, 1892.

1,426. C. G. Moor. Penistone. Improvements in electrical batteries.

1,436. J. Y. Johnson. London. Improvements in friction driving gear for dynamo-electric and other like machinery. (A. de Bovet, France.)

1,442. T. Parker and J. Wakefield. London. Improvements in the manufacture and production of electro-plated metal sheets or articles.

1,459. W. White, J. Radcliffe, and F. W. Cooke. London. Apparatus for adjusting commutators of dynamo-electric machines and motors to varying speed.

1,464. T. Jenner. London. Improvements in holders or sockets for incandescent electric lamps.

January 26, 1892.

1,484. J. B. Entz and W. A. Phillips. Manchester. Improvements in and relating to secondary batteries.

1,497. A. Shiels. London. Improvements in couplings for electric wires.

1,557. R. Threlfall. London. Improvements in electro-magnetic apparatus for producing a reciprocating motion, and for supplying intermittent electric currents for that purpose.

1,580. S. M. Mathews. London. An improved electric low-water alarm.

January 27, 1892.

1,626. R. G. Evered. London. An improvement, or improvements, in the holders or carriers of electrical incandescent or glow lamps.

1,641. A. Siemens. London. Improvements in electro-motors for electrically propelled vehicles.

COMPANIES' MEETINGS.

Anglo-American Telegraph Company (Limited).

The ordinary half-yearly general meeting of this Company was held at Winchester House, Old Broad-street, on the 29th ult., under the presidency of Mr. Francis A. Bevan.

Mr. J. C. SMITH read the notice convening the meeting, in the absence of the secretary (Mr. T. H. Wells), who was absent through illness.

The CHAIRMAN then said: My first duty in addressing you this afternoon is to express my regret that our Chairman (the Marquis of Tweeddale) is, unfortunately, prevented from taking the chair as usual, owing to illness. We have also to regret very much what we have heard respecting another Director of this Company, our old and valued friend, Mr. Cyrus Field. I am sure I am expressing the feelings of this meeting when I say that we heartily condole with him in the great trouble which has come upon him towards the close of his life, and we earnestly wish that he may yet be restored to health and strength. We can never forget that it was mainly owing to Mr. Field's skill and pertinacity that Atlantic telegraphy was ever successful. In spite of repeated failures, Mr. Field saw carried to a triumphant result the idea which he had so much at heart. Now, gentlemen, I can quite understand that on reading this report there might have been a certain amount of disappointment at the result of the year's working. When we look into the accounts we find there is almost no increase in the receipts, but I may explain that of the increase of £5,000 odd, about £1,000 was really a matter of account, and that the real increase in the receipts of the half-year was only £1,500 beyond this £4,000 that I am speaking of. I do not know that we can be greatly surprised at this, when we take the state of business into account. I have seen the figures of the Bankers' Clearing House returns for the year. I do not think I am at liberty exactly to mention them before they are published, but when they are published you will see that there has been a falling off in business during the past year of many hundreds of millions as far as the Bankers' Clearing House returns are concerned. That, perhaps, is as good an indication as you can possibly have that there has been much less business transacted during the past year than during the previous year. We know to what this is principally to be attributed—the Baring crisis. We could hardly expect in this state of business that we should be able to maintain the same amount of business as in the previous year, but I am glad to say we have not only maintained the receipts, but they are a little larger than in the corresponding half of the previous year. The increase of expenses is owing to two causes. First of all, we have had to open new stations, in order to meet the competition, which is a very powerful competition; and you know in these days unless people have telegraph stations brought almost to their very doors, it is a question whether they will telegraph at all. We have, therefore, spent some thousands of pounds in establishing new stations, a policy which, I am sure, you will all approve. Besides that, we have had to spend rather more than usual on the repairs of cables. As you see in the report, "the Company's ss. 'Minia' has been engaged during the past half-year in the repair of the 1880 cable, the Brest St. Pierre cable, the North and South Placentia cables, and the Duxbury cable," whereas in the previous half-year we had very few repairs; so that we have had not only to open these new stations for the development of our business, but also to spend more than usual upon our repairs. The result is that the amount available for dividend, I regret to say, is rather less than it was for the previous half-year. But let me just throw a little ray of light upon what appears a rather dark statement. I am glad to say that the new year has opened better. We are able to report that from the 1st to the 28th of this month there has been a daily increase of £50 in the receipts, and if business will only become better, no doubt we shall share in the good results that are sure to ensue. Perhaps, here I may just allude to the latter part of paragraph 4, in connection with the Company's cables. You will see there that the "Minia" has been employed in laying a cable from North Sydney, Cape Breton, to Canso, Nova Scotia, which means 116 miles of new line, to make a most important connection. It brings us into more direct communication with New York than before, it completes the through cable communication between England and New York city; and we have not taken this out of ordinary revenue, but we propose, with your sanction, to take it out of the renewal fund. We have no capital account to which we can debit the amount, and we must ask your permission to debit this amount of £12,000 to the renewal fund. It appears to us that no more legitimate use can be made of the renewal fund than such an expenditure as this. We, therefore, believe that you will be very glad to sanction such an expenditure on account of the renewal fund. I can easily understand that there is a certain amount of disappointment with regard to the dividend, and the Chairman has received letters suggesting that we should increase this dividend by taking something from the renewal fund. It appears to me and my colleagues that this would not be a wise proceeding, and I venture to say this for reasons which I will now mention. In the first place this renewal fund is the very backbone of our Company. If it had not been that we had this large fund behind us when we had that competition with our rivals, I do not know where we should have been. But, more than this, you must recollect that we have now four cables, all of which are rather old. One was laid in 1869, one in 1873, one in 1874, and the other in 1880; and, in case of any serious breakdown, the only source from which we can repair or renew is the renewal fund. At this moment our Brest cable is broken in deep water something over 1,000 fathoms. We cannot say how much it will cost us to repair that cable; we cannot say even whether we can, though probably we can; but I want to ask you to suppose that one of our cables was to be broken and we could not repair it, where are we to get the money to put down a new cable except from this renewal fund? Surely it would be most unwise to whittle away this renewal fund for the purpose of in-

Digitized by Google

creasing our dividends when we have these old cables, and giving to our shareholders that which that they have not really and fairly earned during the half-year. I maintain that that would be an utterly unsound and unwise policy, and that we should not be fit to be Directors of this Company if we were to adopt such a course. Suppose, as was suggested at the last meeting, I think, that our dividend were to be fixed at 3½ per cent., and suppose that we paid such a rate on the present occasion, it would mean taking rather less than £60,000 out of our renewal fund, which we could never get back again, and this in the face of what I have just now stated. I do trust that you will take this into your serious consideration. We must look at the security and safety of our lines. Upon them depends our power of earning, and if we in any way were to risk that we should for ever regret that we parted with money which we could not possibly get back again, and which we have found before, and shall still find, most invaluable. There is just one other point I should like to mention in connection with this rate of dividend. I shall only touch lightly upon it, but it is an important point. We hear sometimes that we compare very unfavourably with our rival, the Commercial Cable Company. We see that they pay a dividend of 7 per cent., that they pay off a large amount of debentures, and put a certain amount to renewal fund; and at first sight gentlemen say, "How is this; how is it that one Company can pay such a high rate of dividend, while the other pays such a small rate?" Well, gentlemen, I do not think that the reason is very difficult to find. Some of us have been in this Company for a great many years—some of us from its inception—and we remember that, notably in 1873, when this Company took over the Newfoundland Company and the French Company, as it is commonly called, a certain amount of bonus stock was created, with the full concurrence of the shareholders, and, as it seemed at the time, wisely; but we cannot forget that the result of that is that we have to pay a dividend not only on the amount in sovereigns that you have invested in this concern, but also on a large amount of capital that has not been invested at all, and that if the real capital of the Company was what the market value says—which is, I believe, about the fair value—instead of paying £2. 12s. 6d. per cent., we should now be paying at the rate of 5¼ per cent. Now, I hope you will take this into consideration. We are certainly overweighted with our capital at present, and we are put in a position of having to pay on a very large capital as compared with that of our rivals; and therefore I say that the comparison, after all, is not so unfavourable, especially when you take into account the further fact that the Commercial Company have two new cables, which do not require the repairs that are necessary in old cables, and that they have an enormous "pull" on the other side from their connections in America. All their affairs, too, have been conducted with great zeal. In view of all these facts, I am not, after all, so despondent when I see them pay a much larger dividend than we do, for I say that our dividend is in reality much larger than appears on paper. Now, gentlemen, as to the future, all that your directors can do is to endeavour to maintain these cables in a state of efficiency, and, as far as possible, to organise their work properly. We have been giving special attention to getting the messages transmitted as correct as we can. As I have said, we have been opening new stations, and thus trying to obtain more traffic. We cannot, however, create traffic; we cannot make people send messages who have no reason for doing so. All that we can do is to try and get as many messages as possible by fair and legitimate means, and to maintain our undertaking in a proper condition. This we shall try to do; but I hope that we shall not be asked to pay a dividend which we have not earned, and thus try and give a false impression to the market. In my opinion though, if the market were to see that we were paying a dividend, as has been suggested, out of the renewal fund, we should see the stock fall instead of rise. I do not know that I have anything more to say to you. This is the first time I have addressed you, and I hope you will excuse anything I have said wrongly or out of place owing to want of experience. All that I can suggest to you is that you should do all that you can do to help us. I believe that if our shareholders were as much as possible to try and influence traffic to come to us, they would do something materially to help us. We have a great number of shareholders, and I daresay a good many of them send messages. They also have friends who send telegrams across the Atlantic. If this Company is to be really more of a success it is by our all pulling together. We have all got the same interest in trying to secure more traffic, which means a larger dividend. He concluded by moving a resolution for the adoption of the report and the payment of the dividends referred to therein.

Sir JAMES ANDERSON: I have great pleasure in seconding the resolution.

Mr. SMITH (York) said that the proprietors were much obliged to the Chairman for the observations he had made, but he thought that they were not upon the point which the proprietors would have liked to hear about. He wrote to the Directors on December 28th suggesting the payment of a dividend of 3½ per cent. per annum, but he had no idea at that time that their traffic would turn out so unfavourably. They were now paying the same dividend as was paid last year.

The CHAIRMAN: Last year we paid £2. 17s. 6d. per cent.

Mr. SMITH, continuing, said that he had thought the dividend was the same, but after what the Chairman had said the position in regard to this important point was even worse than he had thought. He wished to know the amount of new business which the new stations had brought to the Company. The Chairman had told them that the Company had established direct communication between England, France, and New York, and that should show some increase of traffic. He had no doubt that if the increase in their receipts went on at the rate of £50 a day they would be able to pay an increased divivend—at least, he hoped so.

A SHAREHOLDER said he thoroughly agreed with the Chairman that it would be most unwise to take any sum out of the capital of the reserve fund, as had been proposed by the last speaker. At the same time, he did not see why the interest on the £1,000,000 of investments forming the reserve fund should not be brought to the credit of revenue, as was generally done in the case of other companies. He supposed that the £12,000 spoken of by the Chairman was already charged against the renewal fund, and in that case the proprietors now had only to approve the course which had been taken by the Directors. He hoped that with the improvement in their receipts since the beginning of the year the shareholders might anticipate receiving a little more.

Mr. CHESTER observed that the renewal fund had been for years so much deducted from the income of the Company, in consequence of which a reduced amount had been paid on their Ordinary stock, while nothing had been paid on the Deferred stock. It had been taken from the revenue of the Company from year to year, and Lord Monck had frequently stated that as soon as the fund amounted to £1,000,000 it should be stopped.

A SHAREHOLDER: That is never done in any Company.

Mr. CHESTER, continuing, stated that the securities of the reserve fund were shown at their cost price of £923,500; but he found by the share list that these securities were worth £973,500. He found that, deducting the amount at the credit of the renewal fund, they only paid a dividend upon £2,200,000.

A SHAREHOLDER: That is the present price of the stock.

The CHAIRMAN: But we have to pay on the larger amount.

Major BIGGE said he understood that the Commercial Cable Company earned 13 per cent. on its capital, although it paid a dividend of only 7 per cent., the remaining 6 per cent. being carried to reserve fund or set aside to redeem its debentures. He supposed that the capital of the Anglo-American Company, before it was "watered," was about £3,500,000, on which 3½ per cent. was paid. He was quite opposed to taking any of the renewal fund for paying the dividend.

Mr. JOHN NEWTON asked whether there was a known example of a modern cable being unrepairable. Was there also a depth at which any of their cables were laid which had prevented them from being picked up with the greatest ease. He did not think that any statement should go forth from their meeting that day to indicate that their cables were not as safe as a railway.

Mr. W. W. THOMPSON stated that he had been at several of the meetings of the Company, and he believed it would be in the recollection of many that their Chairman had said that when the renewal fund came to £1,000,000 it should be closed, and that the interest arising from it should then come into revenue. If that were so, the holders of the Deferred Stock viewed with some surprise the action of the Directors in employing the fund, immediately it amounted to £1,000,000, upon work which, as he held, the fund was not intended for. He maintained that the word "renewal" did not cover the construction of new cables. The Chairman had told them that day that the Company's cables were old compared with others laid in the Atlantic, and, that being so, he considered it all the more reason why the renewal fund should be kept in hand for repairing them when the necessity arose.

A SHAREHOLDER said he quite endorsed what the last speaker had stated—that the shareholders had been informed by the Directors that when the reserve fund, or the renewal fund, amounted to £1,000 000, the interest arising from it should be used for the benefit of the Deferred Stock.

A SHAREHOLDER: For dividend purposes.

A SHAREHOLDER said that he regarded £1,000,000 as quite sufficient for their purposes, especially in view of what had been said as to the perfection with which cable laying and repairing were now carried out. He inquired what was being done in regard to the lawsuits that were going on.

The CHAIRMAN: I will endeavour, as far as I can, to try and answer some of the questions which have been asked The first gentleman who addressed us was Mr. Smith, who, I am very glad to see, has not moved the resolution which he proposed to bring forward, and I feel that that is an act of kindness on his part. He asked how much business had been brought to the new offices, and the traffic we had gained in Belgium and elsewhere. It is very difficult to ear-mark the traffic, but if we could do so, as we can at the offices, it would not be wise to publish the information at a meeting, because if we had gained at any particular place it would only induce our rival to redouble their efforts there. I daresay Mr. Weaver could enlighten us, but I feel sure that you would not wish me to tell you, if I could, the amount of traffic we have gained at any particular new office. Another point raised by several gentlemen was with reference to the remarks I made about the "life" of cables. Now, this is a very difficult question. Mr. Newton spoke of modern cables. I do not quite know what he meant by modern cables—how far back he calls a modern cable. All cables, in one sense, are modern, but no doubt improvements have lately been introduced, and the probability is that the later cables are better constructed than the older ones. As to the older cables, however, I must remind the meeting that, so far from our cables lasting for ever, three of the cables we originally laid have so far perished that we are not making use of them, and that they are beyond repair. As we have only existed since 1866, and as three of our original cables have gone, I think we should bear in mind that it would not be safe or wise to say that our cables were as durable as the iron roads mentioned by Mr. Newton. We believe, and we can see from experience, that, generally speaking, these cables can be picked up and mended; but sometimes they cost a great deal of money. I daresay you will remember that in the case of one cable that we picked up it cost us £90,000 to do so. I should be very sorry to depreciate our property in any way, but it would be unwise to treat cables at the bottom of the sea as we treat iron roads on dry land. Mr. Smith spoke of our expenses. I do not know whether he knows how many men we employ, but we have a staff of some 300, exclusive of messengers, and many of these men have necessarily to be rather highly paid, because they must be scientific men and men with a certain amount of experience. I do not think that anyone

Digitized by Google

who conducted these cables could do so much more cheaply than we. I was sorry to hear the remarks he made rather depreciating the services of Mr. Weaver. If there is any man to whom this Company is indebted it is my friend Mr. Weaver, and I confess that it was with pain I heard one of our shareholders hint that Mr. Weaver's services are too highly remunerated. Mr. Weaver has given his help, his strength, his time, ability, and skill for the benefit of the shareholders; and I am extremely sorry that any remarks should have been made tending to depreciate Mr. Weaver's services. Respecting the renewal fund, a good many remarks have been made, and I must be somewhat careful what I say on this point, because everything that a Chairman says with reference to this matter is evidently remembered, treasured up, and recorded, so that it comes up at a later meeting in case he makes a slip. You have spoken about the interest of the renewal fund being added to that fund. Now, during the last four years that fund has been credited with £30,000 a year for interest, making £120,000, but during the same four years it has been debited with £20,000 a year, or £80,000 in all; and, therefore, during the last four years the fund, instead of increasing, as you might imagine, by the whole amount of the interest earned, has really only increased by £40,000, the remainder of the interest having been applied to renewals. I think this statement will show you that the Directors have not been adding to this fund in the hand-over-hand style which might at first be imagined. We have only had £10,000 a year really to add to the fund. As to the value of the fund itself, surely you would not wish us each time we come before you to give you the market value of the fund on the day. The actual market value of the investments constituting the renewal fund on December 31st, to which date the report goes up to, was about £40,000 more than the cost price, at which we have put them: and they have increased, according to Mr. Chester's calculations, by another £10,000 in the last 28 days. He may be perfectly correct, but we cannot say whether it might not be largely depreciated by some great catastrophe in the next two or three months. It would not be wise—it would be inconsistent with the principles of business, to show our stocks always at the market price of the day. We have taken them as a whole at cost price, and have not written them up by £40,000 or £50,000 of nominal value. In calculating this fund, too, we must remember that some portion of it is cable, and I do not think that that ought to be taken into account. The renewal fund, however, amounts to something like £1,000,000; we admit it, and it is quite an open question whether, when the fund has fairly reached the million, we should not give the shareholders the benefit of the interest. Mind, I say it is an open question. I am not going to pledge myself or the Directors on the point. I have been looking to see what former Chairmen have said, and I find that Lord Monck said that when the fund reached £1,000,000, no more should be taken from the receipts and put to it. He was not then, however, as far as I can tell, speaking of the interest of the fund. I am quite sure that when in our opinion the fund has fairly reached the million we ought to consider and do what we can to give the shareholders the benefit of the net increase which occurs thereon; but please to remember that that has been only £10,000 a year in the last four years. It is not the whole interest of the fund, but the interest subject to reductions for renewals.

A SHAREHOLDER: Renewals and extensions.

The CHAIRMAN: Now I come to that question of extensions. It has been said that the renewal fund was not intended for extensions, and the auditors put in their certificate, "Audited and approved, subject to the above charge of £12,141. 19s. 2d. being confirmed by the shareholders." It was their opinion whether, without the consent of the shareholders, this amount could come out of the renewal fund. If, however, it did not come out of that fund, it could only come out of the balance available for dividend, as we have no capital at all. I do not know what we should gain by carrying this sum to a suspense account. That is a course that is taken when there is an expectation of getting something back; but there is nothing to come back in regard to this outlay. We think that we have acted in this matter for the benefit of the concern generally; and considering that we have this large renewal fund, which some gentlemen are very anxious to get for the benefit of their own pockets, we do really give them the benefit of the fund by expending this money to improve the traffic between the London and New York. Mr. Chester made some remarks which I cannot follow as to the capital value which he had arrived at of the whole property. It is perfectly open to anyone to say that our capital value is £2,200,000; but, if so, we are paying a very high dividend. I believe, however, if our property were sold it would realise far more than this sum, and that that is by no means the value of our property. He also asked about the amount standing on deposit account. That is in hard cash, placed at the bankers for the purposes of meeting your dividend. We have from time to time large out-payments to make, and it seems to me a very small amount to have at your bankers to meet your dividends and any other expenses you might be called upon to bear. With regard to the action in Paris, Mr. Chapman, our solicitor, is here, and I will ask him to reply to that question, as he will be able to do so better than I can.

Mr. CHAPMAN stated that the case in the first instance was heard before the Tribunal of Commerce, whence it went on appeal by the French Company to the Court of Appeal in Paris. The Court of Appeal in Paris, before pronouncing any judgment upon it, remitted the matter to the administrative department, in order that the real meaning of a letter of the Minister of the department which was addressed to the French Company might be interpreted. The decision of the Conseil d'Etat was given last May, and there was no appeal from it. The effect of the decision was to send the case back to the Court of Appeal in Paris, and the case was now pending in that Court. It was hoped, however, that it would be shortly settled.

A SHAREHOLDER: Will that be final?

Mr. CHAPMAN replied that there was the Court of Cassation, which was the highest Court in France on certain points, but whether that Court would be appealed to or not he could not say.

Mr. CHESTER said that he saw it stated in the newspapers that the decision which had been given was final.

Mr. CHAPMAN replied that the decision of the Conseil d'Etat was final, but that was only interpreting the true meaning of the letter of the Minister. No decision had been given on the merits of the thing.

A SHAREHOLDER inquired the amount involved in the case.

Mr. CHAPMAN said that this was a question which it would be impossible for him to answer. The Tribunal of Commerce gave 2,000fr. a day for one period, and 5,000fr. over another period, but the Court of Appeal in Paris was not bound in any way by the decision of the Tribunal of Commerce. The judgment of the Tribunal was on the assumption that the French Company would resume, sooner or later, the performance of the contracts, but they might look upon this now as not at all likely.

Mr. SMITH desired to state that in what he had said about Mr. Weaver he had only been making general remarks on that gentleman's position as Managing Director. He had intended nothing personal in what he had said. The expenditure for the past year was about £5,000 more, and this subject was under Mr. Weaver's control.

The CHAIRMAN, resuming, said: Some one spoke about Lord Tweeddale's energetic management of the North British Railway Company, and I can only say that he is equally energetic in this Company. He seems to have everything at his fingers' ends, and is almost every day at the office. Though he may have a great deal of work to do, he is an extremely energetic and capable man. I may just add that we telegraphed to hear the state of Mr. Field's health, and we have just received this reply:—"2:50 p.m. Field's condition practically unchanged. He is in a very weak state, but all his friends hope for the best." I am sure that that includes all his friends on this side. The speaker then put the resolution to the meeting, and it was carried *nem. con.*

On the motion of Sir JAMES ANDERSON, seconded by Sir ALBERT J. L CAPPEL, Mr. Bevan was re-elected to his seat at the Board, as was also Mr. Charles Burt, on the motion of the Chairman, seconded by Mr. Weaver.

Mr. NEWTON afterwards proposed the re-election of the auditors, Messrs. John Gane and Joshua Dean. He expressed his belief that a good deal of time would be saved at their meetings if some scheme could be carried out for conciliating the interests of the Preferred and Deferred shareholders.

Mr. JOHN BROWN seconded the motion, which was adopted.

The proceedings then terminated in the usual manner.

City and South London Railway Company (Limited).

The ordinary half-yearly meeting of this Company was held on Tuesday last at Winchester House, Old Broad-street, under the presidency of Mr. C. G. Mott.

The SECRETARY (Mr. W. F. Knight) read the notice convening the meeting. The report of the Directors and statement of accounts were taken as read.

The CHAIRMAN, after expressing on behalf of the Board their deepest sympathy with the Royal Family in their great bereavement, by the death of the Duke of Clarence and Avondale, who was present at the opening of the City and South London Railway little more than a year ago, and who had always evinced a great interest in the line, said he regretted that they had to meet again without being in a position to declare a dividend on the ordinary stock. During the first half of the present year they had, in common with many other lines, an unsatisfactory traffic, which on their line was especially affected during the holiday season by the absence of many of their regular travellers. They anticipated that this would have been more than made up by the increase of traffic that they would receive from the almost daily cricket matches at the Oval. Unfortunately, the weather was extremely bad during the whole of that period; and there was hardly a cricket match that was in any way a success, and they got little or no additional traffic from that source. The result was that their average receipts for the first quarter of the year were only £711 a week. After the holiday season was over and people began to get more confidence in their line, their traffic began steadily to increase—so much so that in the second quarter of the year their average receipts were raised to £802 a week. They thought that the want of the increase in the first part of the year might be due to their fares being considered excessive at some periods of the day, and that a reduction of those fares might result in an increased income. They did reduce and vary the fares, and on the whole they felt that so far that reduction had been successful; but in some cases they had since found that they could increase the fares again without losing any of their traffic, and they were taking every opportunity of carrying out that policy. The average fare per passenger in the first half of last year was 1.9d.; in the second half of the year it was reduced to 1.7d., exclusive of the season ticket holders. The difference in the decimal amounted to more than £2,000; but this had been more than made up by the increased number of passengers that they had carried; and, therefore, on the whole half year they showed an increase in total receipts of some £600. When they began to raise the fares, as they did on November 1st last, they introduced a system of season tickets, which had been largely taken advantage of. The number of season tickets was steadily increasing, and he was glad to say that those which had just expired were being nearly all renewed, showing that the season tickets had met the demand, and that the Company were giving satisfaction to the holders. The great fault of the line was the want of sufficient traffic and sufficient receipts. Their receipts per train mile were 2s. 1¼d. Now, the average receipts for the steam railways of England were about 5s. per train mile; in fact, in passenger lines they exceeded that usually. Their expenses per train mile had only been 1s. 7¾d.; those of an ordinary steam railway were 2s. 9d., so that the Company's expenses were very much lower than

Digitized by Google

those of a steam railway. But, of course, their trains did not carry so large a number of passengers as those on an ordinary steam railway. He would deal with this point presently. Their total expenses appeared to be very high. They were always high at the early stages of a new railway. They amounted to 76 per cent. of the receipts for the half-year; but when they compared these figures with those of an ordinary railway, they must recollect that in addition to the usual traffic of steam railways they had to work the lifts which took the passengers up and down—a matter quite extraneous to an ordinary railway—and if they deducted the cost of working those lifts, it would be found that the expenses of the past half-year were reduced to 66½ per cent. of the earnings. If their receipts had also increased, and, instead of being a little over £20,000, had been as much as £30,000, they could have carried that traffic at practically little or no increase of expenditure, their working expenses would have been reduced from 66½ to 45 per cent.—a figure lower than was reached by any steam railway in the kingdom. In the early stages of a railway the percentage of expenses was always higher than it was after the traffic developed. In the case of the London, Brighton and South Coast Company, for instance, their expenses in 1867 were 85 per cent. of their receipts; whereas their expenditure last half-year was 48¾ of their earnings, so that the growth of traffic brought down the percentage very rapidly and very largely. The expenses of the London, Chatham, and Dover Railway Company, about the same time, were 71 per cent. of their earnings. Therefore, so far as their position in point of age was concerned, they were very much in advance of those two Companies. They were only a year old, and those Companies at the time he referred to had been in existence some years. Their expenses this half-year had shown certain decreases which had been, unfortunately, counterbalanced by certain increases on the other side of the account. Some of these were referred to in the report. They had had an increase in the item of compensation. They had had one or two claims brought against them which they thought it was better to settle, although he did not think they were just. The rates and taxes had increased in the half-year to the extent of £152. On the other hand, locomotive expenses had decreased by £388; traffic expenses had decreased by £38; maintenance of the line had increased by £104, and there was a small rise in the general charges. The result was that the expenses as compared with those of the previous half-year, showed a trifling decrease. It would be very interesting, he was sure, after their year's experience, to give them some facts and comparisons in respect of their working, which they were not able to give before. They could not, of course, say for a moment that the present condition of their working was by any means perfect; but they were improving it every day, and they hoped they were going to lessen its cost. He would, however, give them a few of the results which they had learned so far. Let them look first at the locomotive expenses, which formed a question of electricity *versus* steam. Their locomotive expenses were 7·88d. per train mile. Now, the locomotive expenses of the main lines of the country, such as the London and North-Western, the Great Western, Midland, and Great Northern, were something like 9d. per train mile last half-year. But this was not all. Their charge of 7·88d. included the high price paid for coal, its carriage, and cartage to their depôt. In the case of the companies he had cited, the price they paid was that charged at the pit's mouth, and no carriage was paid at all. If they would deduct from their expenses the amount which they would have saved in their coal if they had been in the position of those other companies, it would be found that the cost per train per train mile was reduced to 6·6d. against their 9d. In the case of companies which paid carriage on their coal, such as the London, Brighton, and South Coast, the cost was 10d. per train mile. It would be interesting to consider in this connection what were the advantages they claimed from electricity. They had told them in the report that "after the experience of the past year, there is every reason to be satisfied with the use of electricity as a motive power for the working of this railway, and for a confident belief that when all the details are fully perfected, it will be found to be at once safe, convenient, and economical." Its safety they had proved, because they had had no accidents; its convenience had been proved, and would be far more so in the future than in the past. He would come now to the question of its economy. He had told them that their expenses were 1s. 7¾d. against the usual price on steam railways of 2s. 9d. per train mile. The reply to this was, of course, "Your trains are very much smaller and lighter." That was perfectly true; but they must recollect this, that the average number of people they took in a train last half-year was 47; and they were capable of taking three times that number. The ordinary steam trains all over the country took an average of 45 passengers per train mile, and the rest they carried was dead-weight not paid for. The Board held that instead of running huge trains only partially filled, it was better to run small and lighter trains which held a greater number of passengers proportionately to their weight, and that they had better increase the number of light trains than have few of heavier weight. This was more for the public convenience, and would in the end be found more economical. In an ordinary steam railway it was reckoned generally that a ton weight of carriages would provide seats for three persons. Of course he was not speaking of Pullman trains, but the ordinary ones. For every one ton of weight they might take it that three persons were accommodated. Now, in their trains for every ton of weight they had five persons accommodated. Therefore, in their electrical arrangement they had a decided advantage over a steam railway. He was very much surprised in reading the report of the Metropolitan Railway Company's meeting the other day, to see that that very able and experienced Chairman, Sir Edward Watkin, whom they looked upon as a special expert in railway matters, gave it as his opinion, which was always valuable, before the Metropolitan shareholders that an electric engine could only draw a train equal to its own weight. Let them see how far this was correct. Now, an ordinary steam passenger locomotive, such as was run on our main lines, was reckoned to take three times its own weight behind it; this was to say, that if they took an engine of 80 tons weight it would draw 240 tons behind it. Now, their electric engines at the present time always took three times, and often four times their own weight. They must also recollect that in running over their line they were not simply taking three or four times the engines weight, but taking it up an incline the gradient of which was 1 in 27, and which had a reverse curve of a little over three chains in radius. He did not think that Sir Edward Watkin had an engine on his line that could do that. Therefore, they were clearly surpassing by electricity steam power, having regard to the work done. These were very important facts to have learned. Now, as to their speed. Their average speed of working at the present moment was 13 miles an hour, including stoppages. They reckoned that they would be able by-and-by to work faster; but they must recollect that that was considerably above the average speed which the Metropolitan trains attain in the inner circle, in which they did not run at 13 miles including stoppages. These figures showed clearly that although electricity was only in its infancy—this being the first line of its kind, and only a year in operation, and therefore affording them no real opportunity of testing it—they would see that electric power was not a matter which engineers of to-day could afford to despise. He confessed, having had a long experience, as they knew, of the management of steam railways in this country and elsewhere, that he could not help feeling that the facts they had learned in the past year pointed at no very distant date to the substitution of electricity very largely for steam on the railways of the world. It was always well when they got to a certain point to look back and see what their expectations were when they started an undertaking. If they looked back to their original prospects—he referred to the time when they contemplated running only to the Elephant and Castle — they estimated that there would be a very large traffic. They believed that at the time, and if they followed the advice of the Board and allowed them to carry out the plans they had in view now, he believed that the tims was not very distant when those traffic expectations would be realised, large as they were. If they looked also at the expenses, it would be found that their first estimate of expenses was based on what was supposed to be at the time the most economical mode of working, an endless cable system—they would find that their first estimate rather exceeded the amount at which they were now working. He always considered, after he had gone into it very carefully, that it was very doubtful whether that estimate was not too low. In the second prospectus which they issued they raised it considerably. He did not think it would be possible to work this line with a cable system. The cable system was an excellent one for certain purposes—for steep hills, for example—because there they got the full advantages of gravitation But to work such a railway as theirs by a cable would involve an enormous strain on the cable, which, moreover, would require to be very strong and so heavy that its weight would be probably twice, if not more, the weight of all their locomotives put together. Then the difficulty of working round a curve and the friction involved in working over pulleys on a line of this kind, would be very great. It seemed to him that the expense would be very great If they had a very large weight to move and had all that friction, he did not think they could have such an economical arrangement as they had in electric engines, in connection with which the friction was very small, and which did a large amount of work with a small expenditure of power. He thought, therefore, they would see that they were justified in what they said in the report that the future of electricity was very promising indeed. Most of their line—nine-tenths—was a good line, and well constructed. He was sorry to say that one-tenth, unfortunately, had been an engineering difficulty. He referred to the part at King William-street Station, and the inclines leading to it. The station was too short, the inclines were too steep, and the curves as they came towards it were very heavy indeed. They wanted, if they could, to add another carriage to each train, but they could not do so because of King William-street Station. The inclines leading to it, which involved them in additional expense for additional power, would be quite unnecessary if they could get rid of it. They could work the line cheaper. The station could not be enlarged. It was so placed that they had the Monument in front of them, and they would not be allowed to approach nearer to that structure. The consequence was that they could not widen the station except at great risk and expense. Now they had been considering if they could not in some way get rid of the station and the inclines altogether. It was a very small portion of the line. Fortunately it was not a very expensive portion, and it would be always extremely useful, even if they substituted for it another line. In order to place the line in such a position that they could work it economically and meet the growing traffic, they thought that there were no other means of doing so than by having a through station in the City instead of a terminal one as now. Unfortunately, all the steam railways came into the City with the exception of the Metropolitan and Inner Circle had all terminal stations, and much they regretted that it was so. All the stations which dealt with the City traffic at those termini were every one of them taxed to their utmost with the constantly increasing traffic. It was a problem which it would in the future take the wisest heads to solve. It took them four or five times the time to deal with trains at a terminus than it would at a through station. They knew what a large expenditure the Great Eastern were going to now in widening the Liverpool-street Station; and even when that was done it would only be a few years before they would be in a similar difficulty to that which they were in now. With all this knowledge before them they felt that, before they went to the expense of making an expensive terminal station, it was wiser at once to take advantage of the experience of the past, which had been gained at a vast expenditure of capital on the part of other railways, and get a through line in the City, and that they should make their terminal station where they could get land at a small cost, and have a number of sidings. It took two or three minutes to get a train in and out of King William-street Station. They would see, therefore, the enormous advantage there would be if they could deal with the growing traffic, and the excessive traffic morning

Digitized by Google

and evening, and at a less cost per train mile. They had at present powers far in excess of their immediate wants. They could work a much longer line than they were able to do now. All this pointed to the wisdom and desirability of the plans that they had now deposited in Parliament. They had looked about them to see in what way they could make those plans work as economically as possible. They had arranged with the London, Brighton, and South Coast Company for a station at the bottom of Denman-street; and it would be able to throw upon them an enormous traffic from that Company's station. The promises of that line for traffic were exceedingly good in every way. They felt that, under their present condition, until they were in a better financial position, they might have some difficulty in raising the capital upon proper terms. They had, therefore, taken power to convert such portion of it as might be necessary to an independent Company, so as not to throw the burden on this Company; but this would enable them to make certain arrangements by which this Company would have all the benefit, and he thought he saw their way to find the necessary capital to work it out. The question as to whether it was to be a separate capital could be determined after they got the Bill. He would gladly have postponed their application to Parliament if he could. They had considered every possible means of obviating their difficulty, and it was only under the strongest feeling that they came to the shareholders and said that in the interests of the Company they could not postpone their application to Parliament for a year. They had come to the absolute conclusion that it was essential to the success of the Company that the Bill should go on, and the Directors asked for the thorough confidence of the shareholders in appealing to them to approve of the Bill. If they thought that the Bill was not in the interests of the Company, then, as far as he was concerned, he was bound to their decision, but he might say that he was not prepared to carry on the business of the Company if that were so. He was so thoroughly convinced that the future of the line was perfectly assured if the Bill went on, and was risked in a most serious manner, if it did not, that he was prepared to base his position entirely on the question. He concluded by moving the adoption of the report and accounts.

Mr. S. HANBURY seconded the motion.

Mr. DRAKE thought that their small enterprise should not be compared with other enormous railway undertakings. Their profits were creeping up, and he hoped that with a little more economical management they would eventually attain a fair remuneration for the money expended.

Mr. MIDDLETON said that he had taken great interest in the working of the line, and he was very pleased to corroborate the Chairman's figures that the price per train mile had gone down very considerably since the previous half-year. He believed that they had reduced the working expenditure from £17,000, to about £15,000. He only wished to impress upon the Board that there was still scope for a considerable reduction in the item, and he trusted that their energies would be rather devoted to that than to any scheme of extension.

Mr. VAN LAREN said that they had been told that electrical traction was a success and perfectly safe; but how was it that their shares stood at the figure they now did?

The CHAIRMAN said he could assure the shareholders that, so far from considering electricity a failure, he considered, from what was known of it, that it was a most decided success in point of locomotion, and promised to be in every way a most satisfactory mode of working this line of railway. They could not be supposed to get a dividend until they equipped the line. They had only been at work one year. During that time they had not only paid their debenture interest, but they had carried forward an amount which might have been distributed as a small dividend; but they did not think it desirable to do so, because if they went on as they proposed, when next they met it would be to declare a dividend on the ordinary stock. He confessed that he did not see any reason to suppose that they would not be in a position to do so provided everything went on as they had arranged. Their opinion in every way was that electricity was a satisfactory power. As to the various stoppages of the line which had taken place he must remind them that they were under the glare of the light of public opinion as a new undertaking as to which every possible fault was found. There was no doubt that they had stoppages occasionally—generally from five to ten minutes—and unfortunately they always occurred during the busy times, and arose from the strain which was put upon the motors, and the engines in going up the incline that led to King William-street. It was found that the mode of winding the armatures of the motors was not perfectly satisfactory, and it was there that short circuits took place. That would be remedied at once if they had had a larger surplus stock of engines. They were re-winding those armatures on an improved plan, and they had experienced no breakdown from these. There were a great many of them in use, and they could only re-wind them by degrees. If the passengers were delayed 10 or 20 minutes they wrote to the newspapers and made a disturbance about it; whereas if there was any delay on other railways there was no notice taken of it. He quite agreed with Mr. Middleton that it was desirable to keep down the expenses whenever it could be done. From his own experience and knowledge he thought they would be extremely foolish if the shareholders did not authorise them to carry out the policy which they had most carefully considered.

The resolution was carried.

The CHAIRMAN, who was unanimously re-elected to his seat at the Board, in expressing his thanks for the compliment, said that he had had a great deal of anxiety and work in connection with the line; but he was thankful to say that he now saw daylight through it, and that there was a future for it which would place it in a far better position than any line in the country.

A special meeting was afterwards held to gain the approval of the shareholders of the Company's Bill now pending in Parliament.

The SOLICITOR to the Company explained the various clauses of the Bill requiring elucidation.

The CHAIRMAN then said that the Company had power under their Acts to make a station at the end of Denman-street; and the Brighton Company had agreed that their Company should construct a subway through their station on to that Company's platform, where their principal suburban trains start and arrive. They also proposed to construct two tunnels under the river, with easy inclines, to a central station at the corner of Lombard-street, and thence by way of Moorgate-street to the Angel at Islington, where they would get ample siding room. He concluded by moving the adoption of the Bill.

Mr. HANBURY seconded the motion.

Mr. MIDDLETON moved, and A SHAREHOLDER seconded its rejection.

The CHAIRMAN put the resolution, and declared it carried by twenty-six to five votes.

Mr. MIDDLETON thereupon demanded a poll.

The CHAIRMAN fixed the poll for Tuesday next, from 12 to 2 p.m., at the offices of the Company, King William-street.

A vote of thanks to the Chairman terminated the proceedings.

Central London Railway Company (Limited).

The first ordinary general meeting of the Central London Railway Company was held at the offices of the Company, No. 30, St. Swithin's-lane, E.C., on Wednesday, February 3rd, for the transaction of the general business of the said Company; Mr. F. A. Lucas presided.

Mr. T. MATESDORF (the Secretary, *pro tem.*) read the notice calling the meeting.

The CHAIRMAN said: Gentlemen, I am not going to make a speech, as this is merely a formal meeting, summoned in accordance with the Act of Parliament; and as no shares have been issued, it is practically a meeting of contributors; and so I will proceed at once to the first object of the meeting which I shall have to move. Messrs. E. G. de Crano, F. A. Lucas, H. Mosenthal, and D. Parrish, the first Directors of the Company named in section 31 of the Central London Railway Act, October, 1891, retire from office, under the provisions of such section; but, being qualified, offer themselves for re-election as Directors. I have, therefore, to move

"*That Messrs. E. G. De Crano, F. A. Lucas, H. Mosenthal and D. Parrish be and they are hereby re-elected Directors of the Company.*"

Mr. H. OPPENHEIM seconded the motion.

The resolution was carried without discussion.

The CHAIRMAN stated that that concluded the business of the statutory meeting, and he called upon the Secretary to read the notice of the Wharncliffe meeting.

The SECRETARY then read the notice, which stated that the object of the meeting was "for the purpose of submitting to the proprietors at such meeting a proposed Bill in Parliament to be entitled 'A Bill to confer further powers on the Central London Railway Company, and for other purposes'"

The CHAIRMAN then called upon the Solicitor of the Company to shortly explain the objects of the Bill.

Mr. MORRIS said that, briefly, the position was that by the Act of 1891, the Central London Railway Company was incorporated, with authority to make a railway six miles in length from Shepherd's Bush to Cornhill, in the City of London. By the Bill before the meeting, they proposed to abandon so much of the authorised line as went into Cornhill, and instead to make a through railway, by way of Threadneedle-street and Broad-street, to the Liverpool-street Station of the Great Eastern Railway Company, doing away with the projected central station in Cornhill. It was proposed to connect the Central London Railway at Liverpool-street with the Great Eastern Railway and the North London Railway by means of a subway; that, briefly, was the object of the Bill.

The CHAIRMAN: I beg to move:

"*That the Central London Railway Bill, 1892, as proposed to be introduced into Parliament, be, and the same is, hereby approved, subject to such addition alterations, and variations as Parliament may think fit to make therein.*"

Mr. H. MOSENTHAL seconded the motion, which was at once carried without discussion; and a vote of thanks to the Chairman closed the meeting.

Cuba Submarine Telegraph Company (Limited).

The following is the report of the Directors of this Company for the half-year ending December 31st last, to be presented at the forty-first ordinary general meeting of shareholders, to be held at the offices of the Company, 58, Old Broad-street, E.C., on Wednesday, the 10th inst., at 12 o'clock:—

From the accounts it will be seen that the gross receipts (including the balance brought from last account) amount to £21,677. 2s. 4d., and the gross expenditure (including the half of the annual payment on account of the 1881 cable) to £6,710. 16s. 0d., leaving a sum of £14.966. 6s. 4d. to the credit of revenue account. Of this the sum of £5,000 has been added to the reserve fund, which now stands at £83,000.

The dividend on the Preference shares will absorb £3,000, and leave £6,966. 6s. 4d., out of which the Directors recommend the payment of a

Digitized by Google

dividend on the Ordinary shares at the rate of 8 per cent. per annum, free of income tax, the balance, £566. 6s. 4d., being carried forward to the current half-year's account.

The cables have continued in good working order throughout the half-year. The Company's suit against the Spanish Government at Madrid is progressing.

Annexed to the report is a comparative statement of the Company's traffic for the last two years.

NEW COMPANIES, STATUTORY RETURNS, &c.

ELMORE'S AMERICAN AND CANADIAN PATENT COPPER DEPOSITING COMPANY (LIMITED).—This Company was registered on January 26, 1892, with a capital of £200,000, divided into 65,000 priority shares and 35,000 deferred shares of £2 each, by Harry Ellis, 64, Cannon-street, London, E.C. The objects are to enter into and carry into effect an agreement which has already been prepared and is expressed to be made between Elmore's Foreign and Colonial Patent Copper Depositing Company (Limited) of the first part, Woodhouse and Rawson United (Limited) of the second part, and this Company of the third part, and is to be signed immediately after the incorporation of the Company; to carry on in the United States of America, Canada, and elsewhere, the business of manufacturers of and dealers in copper and other metals, and all metallic alloys or compounds of the same, and all articles made of copper and other metals and alloys; "to carry on the business of supplying electricity in all its branches, and to construct, lay down, establish, fix and carry out all necessary cables, wires, lines, accumulators, lamps and works, and to generate, accumulate, distribute and supply electricity, and to light buildings and places, both public and private, wherever situate; and to carry on the business of electricians, electrical contractors, electrical and mechanical engineers and suppliers of electricity for the purposes of light, heat, sound, power or otherwise, and of manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation and employment of electricity." The subscribers are:—

	Shares.
James Shurmer, 22, Ossory-road, S.E.	100
R. J. Cox, 31, Railton-road, Herne Hill, S.E.	1
D. R. Allen, 2, Gordon-terrace, Sydenham, S.E.	1
John J. Atkinson, Cosgrove Priory, North Hants	500
William Elmore, Worcester House, Walbrook, E.C., electro-metallurgist	500
John A. Ewen, 11, Bunhill-row, E.C., merchant	500
Frederick L. Rawson, 3, Kensington Court, W., electrical engineer	500

The number of Directors, exclusive of local and Managing Directors, shall not be less than three nor more than nine. The first Directors of the Company shall be elected by the subscribers to the memorandum of association, or a majority thereof, by writing under their hands. Qualification: shares or stock of any denomination in the Company of the nominal amount of not less than £500. The remuneration of the Directors shall be £200 per annum each, with an additional £200 per annum for the Chairman and £100 for the Vice-Chairman, together with 10 per cent. commission upon the net profits in any year remaining after payment of a dividend of 30 per cent. upon the priority shares of the Company; and such remuneration shall be divided between them in such proportion as the Directors may determine.

BENRY TOOLEY AND CO. (LIMITED).—This Company was registered on January 30, 1892, with a capital of £10,000, in £5 shares, by A. P. Honeyman, 9, Bennett's-hill, Birmingham. The objects are to acquire and carry on the business of military weapon manufacturers, mechanical and electrical engineers, founders, machinists, &c., carried on by Henry Tooley and Co., at the "Times Works," 65 and 66, Weaman-street, Birmingham, and 59, Rue Meslay, Paris. Registered without Articles of Association.

TWEDDELL'S SYSTEM (LIMITED).—A Company has just been registered, with the above title, to purchase and take over as a going concern the business of Ralph H. Tweddell, of 14, Delahay-street, Westminster, London, S.W., engineer, and to carry on the business (amongst others) of consulting engineers, ironfounders, mechanical engineers, electrical engineers, &c. It has a capital of £10,000, divided into 200 Six per Cent. Preference and 800 ordinary shares of £10 each, and was registered on January 25, 1892, by Waterlow Brothers and Layton (Limited), 24 and 25, Birchin-lane, London, E.C.

BRITISH TANNING COMPANY (LIMITED) (TANNING BY ELECTRICITY).—The annual return of the above-named Company, made up to January 1, 1892, was filed on the following day. The Company was registered on April 10, 1889, with a nominal capital of £70,000, in £1 shares, to purchase, or otherwise acquire, certain letters patent for the United Kingdom of Great Britain and Ireland, granted to E. Worms and J. Balé, No. 9,515, on July 5, 1887, for an invention for an improved process and apparatus for tanning by the aid of electricity, and to develop and turn to account the same. At the time of making up, 35,140 shares had been taken up, the full amount called upon each, resulting in the payment of £33,732. 10s., leaving £1,407. 10s. in arrears. Registered office: 17, Basinghall-street, London, E.C.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—The annual return of the above-named Company, made up to January 5, 1892, was filed on January 12th following. The Company was registered on May 29 1889, with a nominal capital of £500,000, divided into 49,900 ordinary and 100 founders' shares of £10 each, to acquire and carry on certain businesses, particulars of which were not given, and to construct, establish, and carry on any works, machinery and apparatus for lighting streets and other places, public and private, by electricity. At the time of making up all the shares had been taken up, and upon 45,100 shares the full amount had been called, resulting in the payment of £442,790, and leaving £8,210 in arrears. The remaining 4,900 were issued and considered as fully paid. Registered office: Worcester House, Walbrook, London, E.C.

FOWLER-WARING CABLES COMPANY (LIMITED).—The annual return of this Company, made up to January 1, 1892, was filed on January 6th following. The Company was registered on August 13, 1889, with a nominal capital of £200,000, divided into 39,700 ordinary shares of £5 each, and 300 founders' shares of £5 each. At the time of making up 20,000 ordinary and 300 founders' shares had been taken up, the founders' having been issued and considered as fully paid. Upon the ordinary shares £4. 10s. per share has been called, resulting in the payment of £89,850, and leaving £150 in arrears. Registered office: Victoria Mansions, 32, Victoria-street, Westminster, London, S.W.

PHONOPORE SYNDICATE (LIMITED).—The annual return of the above-named Company, made up to January 5, 1892, was filed on January 12th following. The Company was registered on December 10, 1887, with a nominal capital of £90,000, divided into 60,000 ordinary and 30,000 deferred shares of £1 each, to acquire certain letters patent and inventions, trade marks, &c., and to establish and carry on the trades and businesses of manufacturers of electrical batteries and other apparatus. By a special resolution passed December 22nd, 1890, and confirmed January 15, 1891, the capital was raised to £100,000 by the addition of 10,000 ordinary shares of £1 each. At the time of making up 90,000 shares had been taken up, of which 39,025 ordinary, and 30,000 deferred shares, had been issued as fully paid. The remaining 20,975 ordinary shares have had the full amount called, and all calls paid, amounting to £20,975. £676 has been paid on 676 shares forfeited. Registered office, Blomfield House, London Wall, E.C.

CITY NOTES, &c.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended January 31st amounted to £823, as against £703 for the corresponding period of 1891, an increase of £120. The total receipts to date, from January 1, 1892, are £3,650, against £3,330, in the corresponding period of 1891, an increase of £320.

CUBA SUBMARINE TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January were £3,500, as compared with £2,439 in the corresponding month of last year.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January, 1892, were £2,195, against £2,147, showing an increase of £48, as compared with the corresponding period of 1890.

EASTERN TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the month of January amounted to £63,436, and to £60,005 in the corresponding period of last year, an increase of £3,341.

EASTERN EXTENSION TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the month of January, 1892, amounted to £42,805, against £46,575 in the corresponding period of 1891.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY (LIMITED).—At a Board meeting on Tuesday it was resolved:—"That a payment on account of the dividend of the current year be made: On the 89,261 shares, £3 paid, of 5s. 3d. per share; on the 5,000 fully paid shares, allotted to the Edison Company, 8s. 9d. per share; on the 12,139 fully-paid shares, allotted to the Swan United Company, 7s. 8d. per share." The dividend warrants will be issued on the 22nd inst.

ELMORE'S AMERICAN AND CANADIAN PATENT COPPER DEPOSIT COMPANY (LIMITED).—During this week another Elmore Company has been floated, or rather has been placed upon the market, and notwithstanding the fact that previous Elmore issues have not realised the sanguine results anticipated by the promoters. The Directors of the present Company opened their lists on Monday last, and closed them the same day at four o'clock. The American and Canadian Elmore Company has been registered, with a capital of £200,000 in 65,000 priority shares and 35,000 deferred shares, both of £2 each. The Chairman of the Company is Sir Francis de Winton, and the Messrs. F. E. Elmore and A. S. Elmore are the consulting metallurgical chemists. The offices are at 64, Cannon-street, and the secretary is Mr. J. Shurmer. The objects of the Company are similar to those of the Foreign and Colonial Elmore Company, and the prospectus is chiefly noticeable for the details given of the dividends which are expected to come from the sale of the patents to subsidiary companies. It is not the intention of this Company to work the process itself (the prospectus states), further than the erection in New York of a plant of sufficient size to demonstrate on a working scale the merits of the invention. The other points of the prospectus are similar to those of previous Elmore issues, with which our readers must by this time be familiar. The press have been informed that letters of allotment were posted on Tuesday evening. The applications are said to have been very numerous.

NORTH METROPOLITAN TRAMWAYS COMPANY (LIMITED).—At the half-yearly meeting, held on Wednesday, Mr. G. Richardson, the chairman, said that the arrangements entered into with the General Electric

Digitized by Google

Power and Traction Company (Limited) for working the Barking-road section by electricity were still in operation, and during the last half-year 38,631 miles had been run.

VENEZUELA TELEPHONE AND ELECTRICAL APPLIANCES COMPANY (LIMITED).—Coupon No. 3 of the Five per Cent. Mortgage Debentures of this Company, due January 31st, will be paid, free of income-tax, upon presentation to the Consolidated Bank (Limited), Threadneedle-street, London, E.C., or at the banking house of Messrs. Westendorp and Co., Amsterdam.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The traffic receipts of this Company for the half-month ended January 31, 1892, were £2,735, as compared with £3,791 for the corresponding period of last year.

THE LIVERPOOL ELECTRIC ASSOCIATION FOOTBALL CLUB.—The above club held their second annual dinner at the "Eagle" Restaurant, Castle-street, Liverpool, on Saturday last. The dinner was preceded in the afternoon by a football match between the married and single members of the club, which the former won by four goals to one. In the evening the party, numbering about 80, included Mr. A. Bromley Holmes, Managing Engineer of the Liverpool Electric Supply Company (Limited), Mr. B. H. Collins, Secretary, Mr. A. Clough, Works Manager, and Mr. Naftel, Chief Electrician. The dinner was followed by a miscellaneous entertainment.

THE ELECTRICIAN:

A WEEKLY ILLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 717.—Vol. XXVIII. FRIDAY, FEBRUARY 12, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/6*

NOTES.

The Corporation of Bradford certainly deserves congratulations on the satisfactory progress which is being made in the electric supply which they have undertaken; and there seems to be every probability that another half-year will wipe off the losses of past years, which were inevitable in the beginning of such an undertaking. The average price of coal being 7s. 7d. a ton delivered at the works, no doubt tells favourably on the expenses; but the two-wire system, which is still employed, must somewhat handicap the concern, especially as regards the capital account. We are unable to go closely into the figures, as invited by the Chairman of the Committee, since the details have not yet reached us. The ·58d. for coal per unit represents about 14½ lbs. per unit, which is rather more than double the quantity used at the best London stations. Of course, an engineer would not be so careful with coal at this price as with the best Welsh that has to be used in London. We do not, however, attach great importance to this item, and would rather see some of the items relating to cost of management and distribution.

Some months ago we called attention to the fact that Mr. C. P. Steinmetz had discovered a very simple empirical formula, expressing the loss of energy in iron cores due to hysteresis. The numerical results obtained by Prof. Ewing for different magnetisations showed, on examination, that the loss of energy during a magnetic cycle was proportional to the 1·6th power of the maximum density of magnetic lines during that cycle. Mr. Steinmetz has recently made an exhaustive analysis of the phenomenon of hysteresis, with the view of putting this useful working formula to a thorough test. His Paper, an abstract of which we publish this week, is of considerable interest on account of the importance of the phenomenon itself, and because the only thorough investigation of it yet made was carried out by Prof. Ewing more than seven years ago, when the practical bearing of the phenomenon was but little appreciated. There is, however, one characteristic of the present experiments which makes them especially valuable; many of them have been carried out with alternate currents, the iron losses being directly measured with alternate-current instruments, instead of by static methods, such as Prof. Ewing used. The agreement between Mr. Steinmetz's results and those of Prof. Ewing is as satisfactory as could have been reasonably expected, and may be said to form the first proof that the static method yields results applicable to alternate-current work. A difficulty arises in interpreting the results of the present experiments, owing to the need of separating the losses caused by eddy currents from those due to hysteresis proper; but this difficulty appears to have been surmounted, and the result is to show that Mr. Steinmetz's law—that the loss of energy in a magnetic cycle is proportional to $B^{1.6}$, where B is the maximum induction density—may be relied upon for all kinds of iron. The experiments by means of which Mr. Steinmetz has established his law are exceedingly numerous, and we have not thought it necessary to record them all, as the practical result of the work is completely summarised in the constants found for the different samples of iron tested.

While endeavouring to maintain unbiassed opinions on most controversial matters connected with engineering and science, we may be blamed by some enthusiasts if we allow our impartiality to extend to the metric and decimal question. Two of the most prominent men who have resisted the attempt to decimalize everything are Sir Frederick Bramwell and Mr. Coleman Sellers; but they have been very moderate in the expression of their views, and in this respect contrast favourably with the impetuous spirit which marks the progressive reformer. An extract from an article by Mr. Sellers will be found in another column. We do not believe that the circulars so diligently issued by the Decimal Association carry much weight with manufacturers. We are constantly being told that some semi-barbarous country has adopted the metric system among other fashions of civilization; and that this market or that will only purchase stove pipes that will fit a metrically designed stove, or hatbands a certain number of centimetres in depth. Decimal and metric reformers would consign foot rules to the British Museum; but Mr. Sellers, whose experience as a manufacturer is very large, and who has given the millimetre a fair chance in his factory and found it too troublesome, admits that the metric system is useful in some cases, and advocates the free play of the principle of the survival of the fittest.

If we do not look to the columns of the *Referee* for useful suggestions in electric engineering and apt explanation of scientific phenomena, the fault rests entirely with ourselves. Commenting, as nearly every journal has done, upon Nikola Tesla's experiments, and alluding to the manufacture of light, Lamb's Chinaman who burned down his house in order to provide roast pork is used as an excellent illustration of the

Digitized by Google

wastefulness of our present methods of producing light. The commercial value of the vacuum tube illumination is dwelt upon; and the science of the paragraphs, except those which are based on the leading article in *The Times*, is singularly correct for a non-scientific, we will not say non-technical, paper.

THE various ideas which some of the audience carried away from Mr. TESLA's lecture, and which have appeared in the daily papers, are rather strange. One account is that he has discovered what electricity really is, and that he can manufacture a new kind which gives a very pretty light, that he has "invented" vacuum tubes which need no wires; but there is still some doubt as to whether, if we wish to use these for domestic purposes, we must make ourselves "a channel for a current at something like 50,000 volts." The leading article in *The Times*, from which this expression is quoted, is another example of unusually accurate newspaper science. The "at" instead of "of" just avoids the confusion between current and volts, which is so common. But the article goes on to say—"The vacuum tube glows like the gates of sunrise, but the lecturer feels nothing, though a current of one five-hundredths of the intensity might easily terminate his career." Never was that foreign word "intensity" more vaguely used; we owe a serious grudge to the French nation for it.

MR. TESLA himself is, we understand, not quite prepared to admit that the current which passes through the body is the only element of danger to be considered; but it is difficult to see what other factor than current enters into the question, unless it be that of frequency. Two or three milliamperes at ordinary frequencies can be taken without much discomfort; and with such pressures as 100,000 volts, which Messrs. SWINBURNE and Co. often experiment with, it would be very easy, though very foolish, to run a quarter-horse power motor, using the body as part of the circuit.

Bermondsey Vestry.—At the next meeting of this Vestry the surveyor will bring up an estimate of the cost of lighting the streets by electricity.

The Charge of Steam Engines and Boilers.—Notice has been given in the House of Commons of two Bills to require certificates from persons in charge of steam engines and boilers on land.

Coast Communication.—Sir E. Birkbeck has moved to call attention, on March 4th, to the loss of life and property on our coasts and the necessity for improved telegraphic and telephonic communication.

The New Telephone Exchange at Paris.—The Minister of Commerce recently inspected the new telephone exchange now in course of completion in the Rue Gutenberg. The building is entirely composed of iron, stone and glazed brick.

Inverness.—The proposal to light Inverness by electricity has been put aside for a time. At a recent meeting of the Town Council a motion was adopted discharging the committee appointed to investigate the matter, on the ground that the scheme would cost between £30,000 and £40,000. The inquiry cost £143.

The Saunders' Lightning Guard in Operation.—A very severe single shock of lightning and thunder occurred at the Eastern Telegraph Co.'s Station at the Land's End on Tuesday, about 12.5 p.m. Two of Saunders' lightning protectors were fused, probably saving the Lisbon and Vigo cables and instruments. The Malta circuit was not affected.

Glasgow.—At the last meeting of the Corporation, the special committee on electric lighting recommended that the business, heritable property, plant, and machinery belonging to Messrs. Muir, Mavor, Coulson, and Co. should be acquired by the Corporation at the price of £15,000—the Corporation to receive possession on March 1st next. This was approved.

Electric Drills.—Messrs. Bell Brothers, of Middlesborough, have decided to drill by means of electricity in one of their Cleveland ironstone mines. They have previously employed water turbines, oil engines, &c., as a means of working their drills. The drills will be of the Bell, Steavenson, and Clough type, the motors being designed by Messrs. W. T. Goolden & Co.

Larne.—A meeting was held at Larne last week, at which the Town Commissioners explained to the citizens (who had requisitioned the meeting) the steps they had taken to secure the completion of the arrangements with Messrs. Gordon & Co., for the electric lighting of the town. After a lengthy discussion it was resolved that the Commissioners deserved the best thanks of the town for their enterprise and public spirit for introducing the electric light.

Condensers for Electric Light and Power Purposes.—The dielectric employed by Mr. Swinburne in the construction of his electric light and power condensers is, according to a recent patent specification, thin butter-skin paper. The condenser, when built up, is compressed and baked in a suitable oven for several days at a temperature of about 100°C.; it is then immersed in paraffin oil, the vessel containing the condenser being sometimes exhausted before running in the oil to make sure that the liquid finds its way into all the interstices.

Cable Extension.—Another link between the mother country and one of her colonies has been rendered an accomplished fact by the successful completion, on Thursday last week, of the laying of a cable by W. T. Henley's Telegraph Works Company between the Bahamas and Jupiter Inlet, on the Coast of Florida. The Act authorising the construction of the cable was passed last Sesion, and the contract for the manufacture and laying of it was made with the Company, whose cable ship "Westmeath" left England at the end of December last for the Bahamas.

Liverpool.—At the meeting of the Watch Committee of the Liverpool City Council on Monday last, the question of the Provisional Order applied for by the Liverpool Electric Supply Company was under consideration. A letter was read from the solicitors to the Company, expressing willingness to negotiate on the terms suggested at the last Council meeting—namely, that the Corporation should have power to purchase the undertaking at any time after 1896 on giving twelve months' notice to the Company, the purchase to be at a fair valuation as a going concern. No final decision was come to.

Exports of Telegraph Apparatus.—The Board of Trade Returns for January are not satisfactory so far as regards our exports of telegraphic wire, and of apparatus connected therewith. The value of our exports under this head was smaller than in the first month of either 1890 or 1891. The following is a statement for last year and for last month, in comparison with the corresponding periods of the two previous years:—

	1889.	1890.	1891.
Year	£1,038,540 ...	£1,602,205 ...	£1,434,873
	1890.	1891.	1892.
January	£71,686 ...	£238,223 ...	£46,246

Church Services by Telephone.—At the last meeting of the Glasgow Town Council the minutes of the Churches Committee contained the following:—There was submitted a letter from the National Telephone Company stating that they are desirous of connecting several of the leading churches in the city with their telephone exchange, so that their subscribers whose houses are connected with the exchange could hear the services by telephone, and asking permission to place a telephone instrument or instruments in St. George's Church. The committee

Digitized by Google

instructed the communication to be transmitted to the kirk-session of the church for their remarks thereon. The minutes were approved.

The Crystal Palace Exhibition.—On Saturday last a large number of electrical engineers and others were invited to the Crystal Palace to meet the Lord Mayor and the Sheriffs of the City of London. Amongst those who accepted the invitation were Mr. Nikola Tesla, Prof. Ayrton, Prof. Crookes, Dr. John Hopkinson, Mr. Preece, Prof. Hughes, Prof. Silvanus Thompson, Prof. Perry, Mr. R. E. Crompton, &c. After the Lord Mayor had made a close inspection of the Exhibition, dinner was served in the Grand Saloon. Mr. Rait, Deputy-Chairman of the Crystal Palace Company, presided. The Lord Mayor proposed the toast "Success to the Exhibition." He referred to the discreditable financing of the electric light of ten years back, and compared the state of things then with the very satisfactory condition of the industry at the present time. Dr. Hopkinson proposed the toast of "Electrical Science and Industry," to which Prof. Ayrton replied in a humorous speech. Mr. Crompton, Mr. Preece, and Mr. Nikola Tesla also spoke.

Heavy Resistances.—Nothing, says *Industries*, seems easier to design than a resistance capable of taking several horse-power, as all that is necessary is a few yards of spiral iron wire. In practice, however, resistances come out expensive and cumbrous articles. There is, however, a very simple way of making resistances which will absorb large powers without trouble. The required resistance is made up in lead wire, and this is immersed in water. Under 100 volts a little of the electricity crosses by the water, so the current cannot be found accurately by dividing the pressure by the resistance of the lead. The lead does not waste, as one side peroxidises and protects itself. It is surprising what large currents can be taken up in this way. For temporary work a piece of platinoid wire can be used. A spiral some 3in. long, consisting of a few feet of wire, placed in a bucket of water, will take two or three horse-power till the water is boiled away. These methods are so very convenient that they should be more widely known among electrical engineers.

Rockhampton (Queensland).—In November, 1889, the Rockhampton Gas and Coke Company procured an Act permitting them to supply electricity for all public and private purposes. The Company recently issued a circular to find out what demand there was likely to be for the electric light. The townspeople responded so well that the Company have decided at once to lay down an electric plant. Distribution will take place on three systems, viz., for 500 yards in each direction from the central station there will be plain 2-wire distribution at 110 volts. Beyond this the system will be that of alternate-current transformers, and for the street lighting there will be the continuous-current series arc system. A 3,000-light plant will be laid down at once. The supply will begin about July next. The whole of the work has been planned, and will be carried out under the supervision of Mr. A. E. Neal, the company's electrical engineer. The price of gas at Rockhampton varies from 7s. 6d. to 12s. 6d. per 1,000ft., and it is proposed to charge 1s. per B.T.U. for electricity.

Cleaning a Telephone Switch Board with an Exhaust Fan.—On the switch board of the Chicago Telephone Company there are some 188,000 contacts to be kept clean. The apparatus employed for this purpose, says the *Western Electrician*, consists of a ¾ H.P. Edison standard motor, belted to a Sturtevant exhaust fan. Connected to the exhaust pipe is a 5in. hose, terminating in a funnel, the edges of which are padded with felt. The hose is of a convenient length, about 6ft. or 7ft. The motor is equipped with a rheostat and receives current through a length of flexible cable that may be attached to the lamp sockets located at various points around the board. All this gear is mounted, so that it may be easily moved about. In cleaning an operator starts the motor, and slides the funnel over the face of the board. The strong suction from the blower draws all dust and particles of foreign matter through and out of the holes, leaving them clean and bright. The funnel is made of such a size as to cover 100 holes at a time, so two sweeps are enough to take in all the holes on one section of the switch board.

A Telegraphic Centenary.—French telegraphists are proposing to celebrate, by the erection of a statue or bust, the centenary of the invention of Claude Chappe's optical telegraph. Before resigning himself to devising a practicable optical system Claude Chappe made several attempts to enlist the services of electricity; but it is considered probable that the want of a good insulator discouraged him. M. A. Boussac, Inspector General of Posts and Telegraphs, who is president of the Centenary committee, remembers the days when Claude Chappe's eight-arm telegraph was still used. Two movements were sufficient to indicate any one of the 10,000 code words known only to the authorities. About 1852 there was a somewhat curious mixture of systems. By means of the Foy-Bréguet system the Chappe code signals were transmitted electrically as far as possible, and where the electric telegraph terminated the messages were transferred to the old semaphores. Claude Chappe's device may, therefore, be reasonably deemed the progenitor of the present telegraphic system of France. Driven out of his mind by the attacks of his rivals, Claude Chappe drowned himself on January 23, 1805.

The London County Council and the Electric Railway Schemes.—A considerable part of the last meeting of the London County Council was occupied in discussing the report of the Parliamentary Committee in regard to the railway and tramway Bills affecting London which are being promoted during the present Session of Parliament. The committee recommended (*a*) that petitions be presented against the Baker-street and Waterloo Railway, the Central London Railway, the City and South London Railway, the Great Northern and City Railway, the Hampstead, St. Pancras, and Charing-cross Railway, and the Waterloo and City Railway, with a view to securing the insertion of clauses prohibiting the companies from bringing forward their buildings beyond the general line of frontage of buildings in streets; (*b*) that Parliament be asked to refer the underground railway schemes of the present Session to a joint committee or to a special select committee, with power to inquire thoroughly into the question of the future railways of Central London. They also recommended a petition against the Ward Electrical Car Company's Bill. The recommendations of the committee were adopted.

University College, London.—In order to afford increased and improved accommodation for the departments of Mechanical and Electrical Engineering, and of Physics, the Council of University College, London, have decided to enter without delay upon a considerable extension of the College buildings. The addition to the College will form an important block opposite the east end of University-street, with an extension for some distance along the Gower-street front of the College grounds. It is to contain separate laboratories and lecture-rooms for Mechanical Engineering and Electrical Engineering, with rooms for engineering drawing, a dynamo room, and all else that is required for an efficient school of modern engineering. This extension will enable the basement and ground floor of the central wing of the main building, together with a new building to be erected in the inner court, to be devoted to the department of Physics, which has hitherto been very imperfectly provided for in rooms that were originally intended for quite other purposes than those to which they have been applied. The position of the new physical laboratory will be such that it will be as far removed, as is easily possible in the heart of London, from heavy street traffic.

Bradford.—At the last meeting of the Town Council, Alderman F. Priestman, in moving the adoption of the minutes of the Gas and Electricity Supply Committee, said he was pleased to be able to say that the anticipations expressed by him a year before had been amply fulfilled. On the income side of the account stood £3,592 for electricity supplied. That left a balance of £2,001 to net revenue account. On that account there was to pay for interest on loans £545, sinking fund £392, income-tax £92, total £1,030, leaving a net profit for the half-year of £971 4s. 10d. Interest and sinking fund had been paid from the very commencement. The first half-year's loss on the concern was £1,079; the second half-year's, £732; the third half-year's, £315; and the fourth half-year's, £30; total, £2,157. After subtracting from that total £971

Digitized by Google

profit, a loss of only £1,186 remained. The coal consumed during the half-year was 865 tons. The total cost of that coal had been £342, and the number of Board of Trade units sold was 154,431, so that the cost of coal per Board of Trade unit had been ·58d. The average price of coal had only been 7s. 7d. delivered at the works. He hoped these figures would be closely gone into by the electric lighting journals, and that there might be a discussion upon them, so that it mght be seen whether any other station was better than their own, and, if so, why—in order that if they extended their electric lighting plant they might make any change in the system which might appear desirable.

Military Telephony.—During the monster military manœuvres which took place last autumn, in the east of France, the telephone was, by order of the Minister of War, made extensive use of. Batteries being inadmissable, magnetic telephones were alone employed; the receiver being fastened to the *képi*, while the transmitter was held in the hand. A combined receiver and transmitter (50mm. diameter, 400 grammes weight) was also tried. A naked ·6mm. bimetallic wire was used with an earth return. A good earth was made by sticking a bayonet well into the ground. Mounted soldiers connected the earth wire to their horses' bridles, the current going to earth through the horses' hoofs. Two men formed a telephone detachment. One carried the telephones and a rolling drum weighing 2½ kilogrammes and wound with 1,000 metres of conductor; the other had a light bamboo stick, with a hook at the end and another drum of wire. The two men could thus lay 2 kilometres of line. The man with the telephones walked rapidly along unrolling his wire and his comrade followed and placed it as far as possible out of harm's way on branches, hedges, walls and along trenches. In one experiment a 23-kilometre line, with 10 intermediate posts, was laid down in five hours, speech was perfect, and the whole was taken up again in an hour. Earth contacts seemed to have but little influence. During the sham fight of September 7th, a 12-kilometre line worked without a moment's interruption, although an entire cavalry division passed over it. The cost of the system need not be an obstacle, 10 kilometres of line, 10 drums, 3 telephones, and 5 bamboo rods only costing 185 francs.

Electricity v. Gas.—The following remarks of the Chairman of the Gas Light and Coke Company, at the last meeting of the Company, are of some interest:—"They had very carefully looked into the electric light question as it affected them. The most important electric lighting district was formed of what he might call the Bond-street quadrilateral—Bond-street, Regent-street, Oxford-street, Piccadilly, Pall-mall, and the Strand. Their rental from that district in 1889 was £77,675, when the electric lght was more than beginning to make itself felt; and in 1890 the amount fell to £74,947, and last year to £73,538. They had thus lost in a district which was more electrically lighted than any place in the world £4,000 of rental in three years, while the increase in their rental all over their district for last year alone was £92,000. He might say further that they had got out a list of typical consumers in every part of their district—the Houses of Parliament, Marlborough House, the British Museum, the General Post Office, banks, clubs, places of amusement, and large tradespeople; and he found, dealing with this list of 81 consumers, that the rental which they paid the Company three years ago was £91,363, two years ago the amount was £88,323, and last year it was £87,847. This showed, again, that they had lost £4,000 in three years among all these great consumers of the electric light. He thought they had conclusively proved that the electric light was a light of luxury, and was used only by those who did not care about the question of cost. He might say that out of their 215,000 or 220,000 customers, only 2,600 used the electric light, or less than 1¼ per cent. There was, however, plenty of room for gas, the electric light, oil, and candles."

The Sims-Edison Torpedo.—A trial under way of the Sims-Edison torpedo was made at Portsmouth last week from the steamer "Drudge." In its latest form this torpedo measures 31ft. in length, with a maximum diameter of 20in., and is composed of four water-tight sections. Total weight about 1½ tons. The first compartment contains the charge. In the second compartment is stored the cable. The cable is of Silvertown manufacture, and contains two conductors—an annular one which carries the dynamo current for working the propeller motor, steering the torpedo ahead and exploding the charge, and a central one attached to a secondary battery for deflecting the relays in connection with the electro-magnets which actuate the rudder. In order to secure the necessary flexibility the principal conductor is made up of no fewer than 135 strands. The third section contains an Edison motor, which is a two-pole series-wound machine, running at 1,600 revolutions, and developing 33 H.P. The fourth section contains the shaft for working a two-bladed propeller and the electrical gear for controlling the rudder. On the torpedo being despatched from the "Drudge," which was under easy weigh, it commenced to pay out its 3,000ft. of cable. After exhibiting its amenability to control, the torpedo made an almost complete tour of the ship, and with accelerated speed. Owing, however, to a defect in the dynamo, which reduced the current to 17 amperes instead of 30, and to 750 volts instead of 1,200, the speed at no time reached its previous achievements, when an estimated speed of 20 knots was realised. The whole time from launch to stop was six minutes, so that, with the known length of wire deposited by the torpedo in its course, the approximate speed was 13 knots. The demonstration was, however, sufficient to show that the torpedo was capable of being made a formidable engine of warfare, and to satisfy the visitors that its importance for the purposes of defence ought not to be lost sight of.

Chicago Exhibition.—The Royal Commission inform us that the British colonies promise to be largely represented at Chicago. The amounts voted by the various Colonial Governments already nearly reach £75,000, three times the appropriation made by the Home Government—£25,000—and large additions will be made to this total when the other colonies who have applied for space announce the amounts they intend to spend. Canada, for instance, has not yet decided on her expenditure, though she will make an extensive exhibit. The total area allotted to Great Britain and the colonies will probably be about 300,000 square feet, the largest space ever filled by us at any foreign Exhibition except Paris in 1878 (363,600 square feet), and this will have to be increased by the erection of annexes or otherwise if the demands of the colonies are to be even approximately satisfied. New South Wales has already asked for 300,000, the whole amount available, other known demands come up to another 100,000, and as much may reasonably be demanded for Canada, so that a total area of 500,000 has practically been applied for by the colonists alone, leaving out of the question the requirements of the mother country.—The following letter, which appeared in Saturday's *Standard*, doubtless expresses the views of many others besides the writer:—

SIR: I have just read your very able and interesting article in the *Standard* of to-day, with reference to the approaching Exhibition in Chicago; but regret that I am unable to agree with your conclusion as to the desirability of our English manufacturers making large applications for space. Our American cousins are reputed 'cute; but I question whether they have ever done anything much cooler than this. With one hand they shut out our goods by means of duties varying from 50 to over 2 0 per cent., and with the other they beckon us to come and exhibit in Chicago. What can they mean? They evidently do not want our goods, or they would not try to exclude them with prohibitive tariffs. The answer is simple and sufficient. They want to gather together in Chicago a collection of the best products of all the markets of Europe, with a view to reproducing them in their own country. I think, however, that we have been educators of the world long enough, and observations during a recent visit to the United States convince me that our manufacturers will be wise if they refuse to fall into such a palpable trap, and make up their minds to give Chicago a wide berth in 1893, except as visitors.—I am, Sir, your obedient servant, G. F. ASSINDER.—Liverpool, February 4th.

The Lundy Island Cable.—In view of the increasing agitation for an organised system of coast communication, with branch cables to outlying lighthouses and lightships, the following facts with regard to the old Lundy Island cable are of interest:—Various Chambers of Commerce, the Press, and the pilots of the Bristol Channel, declaring that a cable to Lundy was needed, a Company was formed in 1883, with a capital of £10,000, for the purpose of supplying that need. Mr. G. F. Rogers, of London, agreed to lay the cable, and this was

Digitized by Google

done on March 22, 1884, the shore ends weighing 16 tons to the mile, and the main cable nine tons to the mile. The route, from Hartland Point, to Lundy, *viâ* Rat Island, was selected as being the shortest and least expensive. It was soon discovered, however, that being directly in the tideway and on a rocky bottom, the cable was being cut through. The Company secured an annual subsidy of £100 from Lloyd's, who also engaged to establish a signal station, and work the cable at their own expense. Some 60,000 vessels pass the island each year, and it was thought that they would be glad to avail themselves of the opportunity of reporting their whereabouts. The Company were to receive a royalty of two shillings on every message, so that it was anticipated that a fair dividend might be realised and a sinking fund created. Shipowners, however, forgot their promises of support, and shipmasters in many cases either ignored the pennant hoisted at the signal station, or signalled the watchmen not to report them. The Company, in fact, received little else than the subsidy from Lloyd's, and at length, with a broken cable, and broken fortunes, they wound up their affairs. The cable was resold to Mr. Rogers. He had it taken up in the spring of 1891, and removed to London, where it has been thoroughly overhauled and repaired. If a new company, or any public authority, wished to revive telegraphic communication with the island, they would be well advised not to relay it across the tideway, but by a more oblique route to Braunton. At present a ship may be safely anchored at Lundy ; and the owner, unable to obtain information of her whereabouts, may be effecting insurances at ruinous premiums.

Cylinder Oils.—In lubricating steam-engine cylinders, says the *Chemical Trade Journal*, there are two conditions present which are not met with in any other machinery ; these conditions are a high temperature and water. Although water at ordinary temperatures has no action on oils, yet at high temperatures its action is different, especially with the fatty oils. These, when subjected to the combined action of water and high temperature, are decomposed into their two constituent parts, the fatty acids characteristic of the oil or fat and glycerine. The latter passes away with the exhaust, the former remain behind, caking and corroding the cylinder. Hydrocarbon oils have therefore almost entirely displaced fatty oils for lubricating cylinders. Hydrocarbon cylinder oils are almost entirely derived from American petroleum. They are of two classes, the black and the more highly refined green. The crude petroleum is first filtered, then refined by distillation with heat and super-heated steam. The residue is then cooled artificially, and the paraffin which crystallises out, separated by filtration, the residue being sent out as cylinder oil. When a green oil is required, the black oil is taken, filtered again and again through animal charcoal, as well as being treated with caustic soda and sulphuric acid to get all the impurities out of it. The consistency of these cylinder oils is very variable ; their specific gravity averages about 0·890 to 0·895, but is unimportant and is no guide to quality. The flashing point ranges from 530° F. to 580° F. Flash points in cylinder oils are a matter of little moment. Given other more essential properties, an oil of a flash point over 400° F. is safe enough. The property which a cylinder oil should possess above all others, and the one which should be made the standard, is viscosity : if its viscosity is low, its lubricating power is low too ; on the other hand, given great viscosity, then the lubricating power must be good. In the case of cylinder oils especially, the oil must not only have a good viscosity at the ordinary temperature, but it must not lose it in too great a degree when heated. One with a viscosity of 140 (according to Hurst's Standard Viscometer) at a temperature of 180° F. might perhaps be taken as a standard.

The Glasgow Tramway System.—At the last meeting of the Glasgow Town Council a statement was submitted by the Tramways Committee, showing the cost of tramway traction by various systems of haulage :—*Animal traction.* For the year ended 1890, traction on the Glasgow tramways, including maintenance and renewal of the plant therewith connected, in so far as that can be ascertained from the published accounts, cost 6·031 pence per car mile. *Electric traction by accumulators.* The cost of working, based on offers received, and adding thereto the further charges necessary to cover outlays corresponding to these embraced in the cost of animal traction, and also interest at 5 per cent. on the excess of capital required for working by accumulators as compared with animal haulage, amounts to 4·951 pence per car mile. *Cable power traction.* The cost of working, based on offers received, and adding thereto the further charges and interest as before stated, amounts to 5·053 pence per car mile. It would thus appear, the Report goes on to state, that mechanical power by electric accumulators is fully a penny per car mile run less than animal traction, and by cable haulage, on an extended system, there is a saving of rather under a penny per car mile run. Mechanical haulage should be less liable to increased cost from such incidents as are liable to affect animal haulage. For example, provender for the horses on the Glasgow tramways has cost, for the half-year ended December 31, 1891, fully 21 per cent. more than in the half-year ended December 31, 1890, and it is the cost for the year 1890 on which the foregoing figures have been prepared. The increased cost per car mile for provender alone will be about one-third of a penny per car mile run. Of course the cost for animal haulage in Glasgow is an ascertained fact. The cost of mechanical haulage, as before given, although mainly based on offers received, has nevertheless some items, such as maintenance of track, &c., which can be actually ascertained only when such systems of haulage have been in use for some time, but the margin of about a penny per car mile in favour of mechanical haulage should be an ample allowance for such contingencies. The receipts on tramways worked by mechanical haulage are, as a rule, greater per car mile than on cars worked by animal power. The minutes were approved.

Electric Railway Schemes for the Metropolis.—The Parliamentary estimates for the construction of the proposed railway from Waterloo to Baker-street have been prepared in accordance with the Standing Orders of the House of Commons. These estimates, which are signed by Messrs. Galbraith and Church, the engineers to the London and South-Western Railway Company, and Mr. J. H. Greathead, set down the total cost of constructing this line, including £32,000 for contingencies, at £990,000, or at the rate of just under £330,000 per mile, the total length of the proposed railway being three miles six chains. The cost of the actual tunnelling is estimated at £438,435. The erection of the stations will absorb £189,500, whilst laying down the permanent way is estimated to cost £5,000 per mile.—The Parliamentary estimates for the construction of the proposed underground railway from near Waterloo Station to Mansion House-street have also been duly deposited by the promoters. These estimates set out the length of the line as 1 mile 4 furlongs 6·80 chains, and the total cost of construction at £499,769, or at the rate of about £333,178 per mile. Of this sum it is estimated that £144,300 will be required for the acquisition of land and buildings. The cost of tunnelling is set down at £208,615 ; the erection of stations at £66,500 ; and for general contingencies a sum of £46,365 is allowed. These estimates are signed by the same engineers as the Baker-street and Waterloo Railway scheme.—The promoters of the proposed Hampstead, St. Pancras, and Charing Cross Railway scheme have also deposited the Parliamentary estimates for the construction of this railway, prepared by Sir Douglas Fox, C.E., and Mr. J. H. Greathead, C.E. The total cost of constructing this line, with all subsidiary works, is estimated at £1,255,815, of which £1,030,656 is for the main line, 4 miles 4 furlongs in length, from Charing-cross to High-street, Hampstead ; £185,809 for the short line, 6 furlongs 4 chains in length, from under the Hampstead-road to the King's-cross Station of the Great Northern Railway ; £7,150 for the subway under the Strand to connect with the Charing-cross Station of the South-Eastern Railway ; and £2,200 for a bridge for foot passengers between St. Pancras and King's-cross Stations. Of the total cost, it is estimated that £729,860 will be expended in the actual tunnelling. The acquisition of land and buildings will, it is estimated, cost £240,000 ; the construction of stations, £107,100 ; and for general contingencies a sum of £118,170 is allowed.

ELECTROMAGNETIC THEORY.—XXIV.

BY OLIVER HEAVISIDE.

(Continued from page 321.)

§ 119. It is now desirable to say a few words regarding the method of treating vector differentiation employed by Hamilton, and followed by Tait. The latter speaks in his treatise (chapter I., § 33, third edition) of the novel difficulties that arise in quaternion differentiation; and remarks that it is a striking circumstance, when we consider the way in which Newton's original methods in the differential calculus have been decried, to find that Hamilton was *obliged* to employ them, and not the more modern forms, in order to overcome the characteristic difficulties of quaternion differentation. (For the word "quaternion," we may read vector or vectorial here, because a vector is considered by Hamilton and Tait to be a quaternion, or is often counted as one. This practice is sometimes confusing. Thus the important physical operator ∇ is called a quaternion operator. It is really a vector. It is as unfair to call a vector a quaternion as to call a man a quadruped; although, four including two, the quadruped might be held (in the matter of legs) to include the biped, or, indeed, the triped, which would be more analogous to a vector. It is also often inconvenient that the name of the science, viz., Quaternions, should be a mere repetition of the name of the operator. There is some gain in clearness by preserving the name "quaternion" for the real quaternion—the quadruped, that is to say.) The matter is illustrated by the motion of a point along a curve. But it does not appear, from this illustration, where the obligation to depart from common usage comes in.

The subject is, however, returned to more generally in Chapter IV., on Differentiation, where we are informed that we "require to employ a definition of a differential somewhat different from the ordinary one, but coinciding with it when applied to functions of mere scalar variables." Here again, however, a most searching examination fails to show me the necessity of the requirement; or, at least, that the necessity is demonstrated.

To examine this matter, consider for simplicity a function u of a single scalar variable a and a single vector variable $\mathbf{r}$, say

$$u = f(\mathbf{r}, a).$$

Following the common method of infinitesimal differentials, we have

$$du = f(\mathbf{r} + d\mathbf{r}, a + da) - f(\mathbf{r}, a). \quad . \quad . \quad . \quad (91)$$

That is, on giving the infinitesimal increments $d\mathbf{r}$ and da to $\mathbf{r}$ and a we produce the infinitesimal increment du in the function. Here du, $d\mathbf{r}$ and da are the differentials, and it is important to remark, in connection with the following, that they are infinitesimal, and that du is really the increment corresponding to $d\mathbf{r}$ and da.

Now, Hamiltonian differentials have a different meaning. Though they would be denoted by du, $d\mathbf{r}$ and da, yet, being different, we shall here dignify them with brackets, and denote them by (du), $(d\mathbf{r})$, and (da), to distinguish them from the differentials in (91). The Hamiltonian differential (du) is then defined by

$$(du) = n\left[f\left(\mathbf{r} + \frac{(d\mathbf{r})}{n}, a + \frac{(da)}{n}\right) - f(\mathbf{r}, a)\right], \quad . \quad (92)$$

on the understanding that n is infinity, and that (on which stress is laid) the differentials $(d\mathbf{r})$ and (da) are finite and perfectly arbitrary.

That this process is circuitous is obvious, but is it necessary? Let us examine into its meaning, and compare (92) with (91). First, divide (92) by n. We then have

$$\frac{(du)}{n} = f\left(\mathbf{r} + \frac{(d\mathbf{r})}{n}, a + \frac{(da)}{n}\right) - f(\mathbf{r}, a). \quad . \quad . \quad (93)$$

Now, we see at a glance, that (93) and (91) become identical if

$$da = \frac{(da)}{n}, \quad d\mathbf{r} = \frac{(d\mathbf{r})}{n}, \quad du = \frac{(du)}{n} \quad . \quad . \quad (94)$$

The division of the finite differentials (da) and $(d\mathbf{r})$ by n produces infinitesimal results, and the finite differential (du) is similarly reduced to an infinitesimal. Why then not employ the infinitesimal differentials at once, and avoid the circuitousness?

When we proceed to form a differential coefficient, as du/dt, if $\mathbf{r}$ and a are functions of t, or du/da, if $\mathbf{r}$ is a function of a, we see that their values are equivalently expressed by $(du)/(dt)$ and $(du)/(da)$, using the finite differentials; because this merely says that the value of the fraction du/dt is unaffected when the numerator and denominator are each multiplied by the same quantity.

In the above, the reasoning is the same, whether u is a scalar or a vector function of $\mathbf{r}$ and a.

But whilst the differential coefficient comes out the same, yet the differential (du) is not the increment in u belonging to the finite increments $(d\mathbf{r})$ and (da), nor is it anything like it, exceptions excepted.

The above is as fair and as clear a statement as I can make of the difference between common and finite differentials as applied to vectors; and we see that the Hamiltonian plan is only a roundabout and rather confusing way of expressing what is done instantly with infinitesimal differentials. But then the Hamiltonian plan is said to be obligatory. There's the rub! I can only give my own personal experience. After muddling my way somehow through the lamentable quaternionic Chapter II., the third chapter was tolerably easy; but at the fourth I stuck again, on this very matter of the obligatory nature of the finite differentials. I am no wiser now about it than I was then. Perhaps there is some very profound and occult mystery involved which cannot be revealed to the vulgar in a treatise; Hamilton is a name to conjure by. Or perhaps I "began the study of quaternions too soon!" Or perhaps it is only a fad, after all. Anyway, I am willing to learn, and if I live long enough, may reach a suitable age. At present let us return to common infinitesimal differentials.

§ 120. Although we may employ the method of differentials in any equation involving vectors, using the symbol d, and although we may turn it into an equation of differential coefficients by changing d to the scalar differentiator d/dt (for example), as in § 116, yet we cannot usually turn differentials into differential coefficients when the variable is a vector. This is not because we cannot form the expressions $du/d\mathbf{r}$ or $d\mathbf{R}/d\mathbf{r}$, but because they are not differential coefficients when the denominators are vector differentials. This will be easily seen from typical examples. (The failure has nothing to do with the previous question of finiteness or otherwise of differentials.) Let

$$u = \mathbf{ab}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (95)$$

and let the vector $\mathbf{b}$ vary. Then,

$$du = \mathbf{a}\,d\mathbf{b}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (96)$$

and, therefore, $$\frac{du}{d\mathbf{b}} = (d\mathbf{b})^{-1}(\mathbf{a}\,d\mathbf{b}) = (d\mathbf{b})_1[\mathbf{a}(d\mathbf{b})_1], \quad . \quad . \quad (97)$$

where $(d\mathbf{b})_1$ means the unit $d\mathbf{b}$. Here the imitation differential coefficient $du/d\mathbf{b}$ is a fraud, because its expression on the right side of (97) is not *clear of the differential* $d\mathbf{b}$, whose direction it involves. Nor is equation (97) of any particular use, compared with (96).

Again, in the vector equation

$$\mathbf{R} = \mathrm{V}\mathbf{ab} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (98)$$

let $\mathbf{b}$ be variable. Here we have

$$d\mathbf{R} = \mathrm{V}\mathbf{a}\,d\mathbf{b}, \quad . \quad . \quad . \quad . \quad . \quad . \quad (99)$$

and from this equation of differentials we may form $d\mathbf{R}/d\mathbf{b}$ and $\mathrm{V}\,d\mathbf{R}/d\mathbf{b}$; but neither of them, nor any combination of them, is a differential coefficient clear of differentials. Thus,

$$\frac{d\mathbf{R}}{d\mathbf{b}} = (d\mathbf{b})^{-1}\mathrm{V}\mathbf{a}\,d\mathbf{b} = (d\mathbf{b})_1\mathrm{V}\mathbf{a}(d\mathbf{b})_1 \quad . \quad . \quad (100)$$

contains the differential on the right side. And

$$\mathrm{V}\frac{d\mathbf{R}}{d\mathbf{b}} = \mathrm{V}\,d\mathbf{R}(d\mathbf{b})^{-1} = -\mathrm{V}(d\mathbf{b})^{-1}\mathrm{V}\mathbf{a}\,d\mathbf{b} = -\mathrm{V}(d\mathbf{b})_1\mathrm{V}\mathbf{a}(d\mathbf{b})_1 \quad (101)$$

also contains the differential. As a special result the value of (100) is zero (a parallelepiped in a plane): and by equation (52) we may develope (101) to

$$(d\mathbf{b})_1\{\mathbf{a}(d\mathbf{b})_1\} - \mathbf{a}. \quad . \quad . \quad . \quad . \quad (102)$$

But it is (99) that is the really useful fundamental equation,

Digitized by Google

the developments (100) to (102) being useless for differentiating purposes, although true and interpretable geometrically.

Generally, if

$$\mathbf{R} = \mathbf{i}R_1 + \mathbf{j}R_2 + \mathbf{k}R_3 \quad . \quad . \quad . \quad . \quad (103)$$

is a function of

$$\mathbf{r} = \mathbf{i}x + \mathbf{j}y + \mathbf{k}z, \quad . \quad . \quad . \quad . \quad . \quad (104)$$

then R_1, R_2, R_3 are functions, usually different, of x, y and z, and the ratio of $d\mathbf{R}$ to $d\mathbf{r}$ (even in the most general quater, nionic sense), cannot possibly be freed of the differentials dx, dy, dz.

Even when we reduce the generality of the problem by making $\mathbf{R}$ and $\mathbf{r}$ coplanar, say in the plane of $\mathbf{i}$, $\mathbf{j}$, with $z = 0$ and $R_3 = 0$, $d\mathbf{R}/d\mathbf{r}$ is not usually a definite differential coefficient. It only becomes one by special relations between the differential coefficients of R_1 and R_2 with respect to x and y, viz :—

$$\frac{dR_1}{dx} = \frac{dR_2}{dy}, \qquad \frac{dR_1}{dy} = -\frac{dR_2}{dx} \quad . \quad . \quad . \quad (105)$$

This is the vectorial basis of the large and important branch of modern mathematics called the Theory of Functions, which appears in electric and magnetic bidimensional problems.

§ 121. Sometimes it is convenient to have the variation of a vector exhibited in terms of the variations of its tensor and unit vector, or its size and ort. Thus, from

$$\mathbf{R} = R\mathbf{R}_1,$$

we produce, by differentiating,

$$d\mathbf{R} = Rd\mathbf{R}_1 + \mathbf{R}_1 dR. \quad . \quad . \quad . \quad . \quad (106)$$

If there be no variation of direction, then

$$d\mathbf{R} = \mathbf{R}_1 dR\,; \quad . \quad . \quad . \quad . \quad . \quad (107)$$

and if the tensor does not vary, whilst the direction does, then

$$d\mathbf{R} = Rd\mathbf{R}_1. \quad . \quad . \quad . \quad . \quad . \quad (108)$$

Dividing (107) by the scalar $d\mathbf{R}$, we get a proper differential coefficient

$$\frac{d\mathbf{R}}{d\mathbf{R}} = \mathbf{R}_1, \quad . \quad . \quad . \quad . \quad . \quad . \quad (109)$$

provided $d\mathbf{R}_1 = 0$. From (108),

$$\frac{d\mathbf{R}}{d\mathbf{R}_1} = \mathrm{R}, \qquad \mathrm{V}\frac{d\mathbf{R}}{d\mathbf{R}_1} = 0, \quad . \quad . \quad . \quad (110)$$

provided $d\mathrm{R} = 0$, which makes $d\mathbf{R}$ perpendicular to $\mathbf{R}$. But it is as well to avoid forms of this kind (with a vector variation in the denominator), even when by some limitation, as above, we can get rid of the differential. Of course, in (106), without any limitation, we can change d to d/dt (or other scalar differentiator) thus

$$\dot{\mathbf{R}} = R\dot{\mathbf{R}}_1 + \mathbf{R}_1\dot{R}. \quad . \quad . \quad . \quad . \quad . \quad (111)$$

It is this (scalar) kind of differentiation that nearly always occurs in physical applications, and there is no abstrusity about it. See § 116. Nor is there about differentials, provided we do not attempt to make differential coefficients with respect to vectors, or make the differentials themselves finite.

We have also $\mathbf{R}^2 = \mathrm{R}^2$,

which, on differentiation, gives

$$\mathbf{R}d\mathbf{R} = Rd\mathrm{R}\,; \quad . \quad . \quad . \quad . \quad . \quad (112)$$

or, dividing by R,

$$d\mathrm{R} = \mathbf{R}_1 d\mathbf{R}, \quad . \quad . \quad . \quad . \quad . \quad (113)$$

which says that the increment in the tensor is the component along the vector of its vector change $d\mathbf{R}$, whose full expression is given by (106). Using (106) in (113) we get

$$\mathbf{R}_1 d\mathbf{R}_1 = 0. \quad . \quad . \quad . \quad . \quad . \quad . \quad (114)$$

Using (113) in (106) we get

$$d\mathbf{R} = Rd\mathbf{R}_1 + \mathbf{R}_1(\mathbf{R}_1 d\mathbf{R}), \quad . \quad . \quad . \quad (115)$$

or, dividing by R,

$$\frac{d\mathbf{R}}{R} = d\mathbf{R}_1 + \frac{\mathbf{R}_1 d\mathbf{R}}{R}, \quad . \quad . \quad . \quad . \quad (116)$$

all of which results may be geometrically interpreted.

In differentiating the reciprocal of a vector, proceed thus :—

$$d\frac{1}{\mathbf{R}} = d\frac{\mathbf{R}_1}{R} = \mathbf{R}_1 d\frac{1}{R} + \frac{d\mathbf{R}_1}{R}, \quad . \quad . \quad (117)$$

where, for d may be written d/dt, &c.

Another way is

$$d\frac{1}{\mathbf{R}} = d\frac{\mathbf{R}}{R^2} = \frac{d\mathbf{R}}{R^2} + \mathbf{R}d\frac{1}{R^2}. \quad . \quad . \quad . \quad . \quad (118)$$

It may easily be shown, by (106), that these results are equivalent.

Enough has now been said about the meaning and effect of differentiating vectors. The important vector differentiator ∇ deserves and demands a separate treatment.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, February 12th.

PHYSICAL SOCIETY.

5 p.m. Annual General Meeting. After which the following Papers will be read: "On Supplementary Colours," and "On Modes of Representing Electromotive Forces and Currents in Diagrams." By Prof. Silvanus Thompson, F.R.S.

INSTITUTION OF ELECTRICAL ENGINEERS.

7:30 p.m. Students' Meeting at the offices of the Institution. Paper to be read: "Some Notes on Electroplating." By H. B. Little.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read: "Fly-Wheels and Governors." By H. B. Ransom, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening discourse: "Rain, Snow, and Hail." By G. J. Symons, F.R.S.

SATURDAY, February 13th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Matter at Rest and in Motion." By Lord Rayleigh, F.R.S.

MONDAY, February 15th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. II.—4. "Developments of Electrical Distribution." By Prof. George Forbes, F.R.S.

TUESDAY, February 16th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. The Discussion upon the following Paper to be continued and concluded: "Gold Quartz Reduction Machinery." By Alfred Harper Curtis, Assoc.M.Inst.C.E.

SOCIETY OF ARTS.

8 p.m. Paper to be read: "The Forthcoming Exhibition at Kimberley, South Africa." By Lewis Atkinson.

WEDNESDAY, February 17th.

ROYAL METEOROLOGICAL SOCIETY.

7 p.m. Ordinary Meeting. Papers to be read: (1) "Report on the Phenological Observations for 1891." By Edward Mawley, F.R.Met.Soc. (2) "The Untenability of an Atmospheric Hypothesis of Epidemics." By the Hon. F. A. Rollo Russell, F.R.Met.Soc. (3) "The Origin of Influenza Epidemics." By Henry Harries, F.R.Met.Soc. (4) "Note on a Lightning Discharge at Thornbury, Gloucestershire, July 22, 1891." By Ernest H. Cook, D.Sc.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. Paper to be read: "The Pamirs." By Capt. F. E. Younghusband.

ROYAL MICROSCOPICAL SOCIETY.

8 p.m. Presidential Address by Dr. R. Braithwaite.

THURSDAY, February 18th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

CHEMICAL SOCIETY.

8 p.m. Ballot for Election of Fellows. Papers.

FRIDAY, February 19th.

INSTITUTION OF CIVIL ENGINEERS.

1.30 p.m. Students' Visit to the Works of the Chelsea and Lambeth Water Companies, at Molesey, and subsequently to those of the Grand Junction, Southwark and Vauxhall, and West Middlesex Water Companies, at Hampton.

ROYAL INSTITUTION.

9 p.m. Friday Evening Discourse: "Micro-Organisms in their relation to Chemical Change." By Prof. Percy F. Frankland, F.R.S.

SATURDAY, February 20th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Matter at Rest and in Motion." By Lord Rayleigh, F.R.S.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co." *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

NOW READY.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday (out of print); Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., Prof. William Crookes, F.R.S. (Past-President of the Institution of Electrical Engineers); Willoughby Smith (out of print); Prof. von Helmholtz, and Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

COAST COMMUNICATION.

The wreck of the "Eider" has once more called attention to the urgent necessity for telegraphic and telephonic communication between lighthouses, lightships, and coastguard stations, and to the utter inability of even our most powerful lights to pierce a few miles of fog. Both subjects have been repeatedly dwelt upon in these columns. As to coast communication, those of our readers who have given the most cursory attention to the matter are probably aware that the Post Office has long ago formulated a complete scheme for connecting all needful points with their main lines. The result of the deputation to the Board of Trade in June last elicited some satisfactory admissions of sympathy; but the everlasting "non possumus" and the polite reference to some other Government department, formed then the chief burden of Sir MICHAEL HICKS-BEACH'S reply. The saddling of the responsibility upon any particular department was avoided with a skill worthy of a better cause. The Board of Trade had nothing to do with the Coastguard Service, the Coastguard being under the Admiralty. But Sir MICHAEL HICKS-BEACH warned the deputation, lest in a moment of enthusiasm they might be so foolish as to waste time in attempting to get the ear of the Admiralty, that the expense would have to be borne by the Treasury, and definitely recommended them to approach that department. We are not aware whether they acted on this advice; but, at any rate, it would appear from a recent semi-official note communicated to the Press, and from

Digitized by Google

the remarks of the President of the Board of Trade at the banquet of the Chamber of Shipping of the United Kingdom, that an inquiry will be granted.

An immediate and effective improvement in our coast communications is rendered imperative from three points of view—humanity, the safety of our shores in time of war, and the needs of our mercantile marine, one and all, call for a new departure. Indeed, a mistake has perhaps been made in plying wearied Government officials with too many reasons, and in mixing commercial with humanitarian motives. The "Sunk" lightship trials have been dubbed a failure because a good committee reported that electrical communication could be established in such positions; but that the cable service should be discontinued as having been of no real service during the four years over which the experiment lasted. The extension of ordinary ship-signalling has been suggested; but to urge this is only to afford an excellent excuse, which will be seized on at once by the Treasury, that Lloyd's or those responsible for the allocation of the Mercantile Marine Fund ought to see to the whole matter. The admirable telephonic line on the coast of Denmark, by which lighthouses, lifeboat stations, and rocket stations are placed in direct communication with each other, and with the telegraphic system of the country, is largely used by fishermen to convey information about passing shoals of fish, markets and prices, and other matters connected with the fishing industry. But it would never do to bring this forward in attempting to get the Admiralty to move. What has that department to do with fishing-boats except as impertinent intruders on their practice ranges? They would refer the matter to the County Councils. It is estimated that £100,000 would suffice for connecting the stations on the coast with the telegraph system of the United Kingdom. The Navy estimates for 1890-91 included £236,971 for "gun-mountings and torpedo carriages and gear," besides £90,000 for "electrical, torpedo and other apparatus." The estimates for 1891-92 for the same items are £251,000 and £70,000 respectively. Some 700 lives are lost every year not upon the high sea, but close at home on our shores among the rocks and breakers. Mr. Robert Bayly and others have recorded scores of cases in which lighthouse keepers and coastguards have been eye witnesses of awful disasters, but have been either absolutely unable to help, or have been reduced to a vain endeavour to call out the nearest lifeboat, perhaps miles away, by a foot messenger More lives might be saved by the expenditure of this £100,000 than will ever be destroyed by the Brennan torpedo, on which so many thousands have been squandered.

It is argued by officials and others that this most needful extension of the electric telegraph would take away coastguard men and lighthouse keepers from their proper duties. What are their proper duties? The coastguard service already undertakes a variety of duties, some of which have no more connection with naval matters than the probate or divorce matters which are associated with the Admiralty in the Law Courts. It was not until 1856 that the coastguards were transferred to the Admiralty; and even now their incessant patrol of the coast is in the interests of the Inland Revenue and in keeping a lookout for wrecks, rather than in actual Admiralty service. One of the attainments of which most coastguardsmen are justly proud is their skill in signalling. No army "flag-wagging" can compete in speed with the simple semaphore system which many of them employ every day. At the same time they have a good knowledge of the Morse code, and most of them can handle a Morse key and read a Sounder. Telephonic and telegraphic communication between coastguard stations, lighthouses, and lifeboat stations, even if the isolated lighthouses and lightships were not connected, would be of immense service in procuring and arranging help, and the cost of maintenance would be trifling. To connect our rock lighthouses and exposed lightships by cable with the mainland would be a far more costly and difficult task; but we have heard of no experiment which can be said to demonstrate its impossibility. Telephonic and telegraphic communication cannot as yet be satisfactorily carried on without any wire at all; but enough has been done to show that nothing short of a complete rupture need stop transmission over short lengths of line.

As to the question of how best to increase the penetrative power of our coast lights in time of fog, there seems little else to suggest but experiment—persistent experiment. The material and other less substantial rewards which would attend a complete solution of the problem should spur the efforts of scientific men. Prof. Tyndall has recently put forward the idea of causing "sudden and powerful flashes of light to impinge upon fog;" practical mariners favour the idea of a vertical beam; others have proposed an alteration in the colour of the light. Our knowledge of the atmospheric conditions which obtain in time of fog is too meagre to make one suggestion more feasible than another. But the importance of overthrowing the dominion of King Fog renders the cost of continued experimentation a secondary matter.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

Introductory.

It is proposed in these notes to describe the procedure on board ship when removing a fault or break in a submerged cable, and the mechanical gear used in different vessels for this purpose. Further, as regards the electrical tests in use for the detection and localisation of faults, to consider the best and most recent practice, and the various difficulties that occur to the beginner. With a total length of 136,000 miles of cable submerged, and a fleet of 36 steamers employed solely in laying and repairing cable, some idea may be gained of the vastness and importance of this enterprise, and the various interests it involves. Of late years many improvements have been introduced in the tests used for locating the positions of faults in cables, and these have meant a considerable saving to the various companies in cost of maintenance. With a vessel, say, of only 300 nominal horse-power, where the coal bill alone amounts to 25 tons per day, the fact of saving a week on repairs by good methods and machinery is of no small importance to a company and its shareholders.

Before entering into the details of ship practice, it may be as well in this introduction to enumerate some of the more salient points in the electrical tests employed, as they are likely to impress the beginner, and to make some allusion to the kind of improvements that have recently been introduced. In the first place, the method devised by Sir Henry Mance, in which the interfering effects of polarisation and earth currents are neutralised without the necessity of reading to false zero, marked a distinct advance on that of Lumsden, if only for the reason that the test could be carried out with the current in one direction only, while the latter required reversals, and therefore the greatest care in avoiding errors due to deposition of salts at the fault.

Further, the means of localising partial earth faults without the assistance of a return cable have been greatly improved by two methods. The Blavier test has long been known to yield doubtful results by itself, especially when the fault is near the testing end, but it serves the purpose of giving preliminary approximations for use in the more accurate methods. One of these improved methods is the earth overlap of Messrs. James Anderson and A. E. Kennelly, who add a resistance to the cable on the faulty side, so that the testing currents from both

Digitized by Google

ends of the line encounter equal resistances on each side of the fault. Two such readings with the distant end earthed, and similar battery powers each end, give results which approach very closely the conditions and accuracy of the Varley loop. Mr. H. Kingsford, in another method, tests from one end only, as in the Blavier, but adds a resistance to the line, when the distant end is free, such that the current through the fault is the same strength as when the cable is earthed. In both these methods the principle involved in the improvement consists in maintaining the resistance of the fault constant during a pair of observations under different conditions; and this is done by using the same strength of current through the fault in the two cases. It has long been known that an increase in the testing battery power reduces the resistance of a fault, but it was not until the above methods were devised that the change in resistance of the fault caused by a difference in current passing through it, in two observations, was taken account of. Again, Mr. Kennelly has made a great advance by his discovery of the law connecting the resistance and exposed area of conductor in sea water, with the strength of current passing through the exposure. While not applicable to small faults, where the free evolution of gas is prevented by the adhering deposition of salts, it has proved of the greatest value and service in the localisation of total breaks or fractures of the cable. Mr. Kennelly has also modified the method in such a manner as to exclude all chances of error in observing the false zero, by working to true zero with one additional observation on the bridge.

While these improved methods in localisation are most generally used when a fault presents itself, it is often advantageous to use some of the older methods in order to check the results. And not only for this reason but perhaps, what is more to the point, for the sake of observing the behaviour of the fault. It is on the behaviour of the fault as indicated by the movements of the spot of light on the scale that old practitioners chiefly rely for arriving at an estimate of the fault's resistance. The steadiness or otherwise of a balance, the appearance or not of polarisation with a zinc current, and the rapidity of polarisation with a copper current are points beyond the mere figures read off from the Wheatstone bridge which it is desirable to notice, for, by these effects a pretty fair idea can be formed of the size of the fault and the amount of resistance to allow for it.

It is, of course, the best practice, when time permits, to test by three or more different methods as a check on each other, and it is, therefore, necessary to keep familiar with all the most approved methods. There is generally time to carry out a reliable series of tests by more than one method on shore before the ship is able to reach the position and require watch kept on the line, and also on board ship when picking up to the fault; but it frequently happens during repairs in deep water or rough weather that a bridge test is limited to a minute or 30 seconds on account of the dangerous strain on the cable when both ends are hanging to the ship. It is, therefore, desirable to attain a certain degree of smartness in using the bridge and keys, although, of course, reliability must be the first consideration.

Opportunities are generally afforded to men on the general staff at a cable station, who are so inclined, to carry out tests on the cables. The first practice is usually on cables in good condition, where the resistances of the conductor and insulator are periodically tested. The records of the state of insulation of a cable, kept in this manner, are particularly useful in giving due warning of any cause at work tending to bring about a fault. Signalling can generally be carried on with more or less difficulty through a cable with a fault making only partial earth; and it frequently happens that no appreciable difference is observable in the signals when the starting of a small fault has considerably lowered the insulation resistance. In such cases, therefore, the periodical test gives notice of the incipient stages of a fault, where the signals transmitted would not do so until the fault is considerably developed, and it is often located a sufficient time beforehand for its removal to be effected before it become a cause of serious delay to the traffic. The first thing to do when the periodical tests show a fall in the insulation is to free at the cable house, and make sure that the defect is not in the land line, and ask the other end to do the same.

The records of the conductor resistance tests are chiefly of use in furnishing the correct resistance per knot required in localising any fault that may occur. It is customary for the ship, after effecting a repair, to inform the stations at either end of the corresponding increase in length of the cable, and with this corrected length the resistance per knot of the conductor and capacity per knot of the dielectric are determined anew and confirmed periodically. A cable when first laid is made up of at least three different types, and may have other types differing in resistance and capacity spliced into it at the time of laying. The paying-out log, together with the cable chart, furnish accurate information of this, while after a repair has been effected the type of cable inserted is always entered on the splice list. While differing in types it is of considerable assistance to have the mean resistance and capacity throughout the entire length.

The resistances of the conductor and insulator are usually measured by the bridge and deflection tests respectively. In carrying out these tests an acquaintance is made with earth currents, steady or otherwise, most frequently otherwise, which are generally prevalent in cables even when insulated at one end.

The conductor resistance test, on a perfect cable, when interfered with by an earth current, affords excellent practice of the kind afterwards required in fault testing. The interfering current, when unsteady, has to be watched by itself before and after balances are attained on the bridge, in order to judge a fair mean to allow for a false zero, and good practice can in this way be made of balancing to false zero. Acquaintance is also made with the fact that results can be arrived at within closer limits of accuracy, when the resistances in the fixed arms of the bridge (or ratio arms) correspond most closely to the resistance of the cable. Also, after some amount of usage of the bridge, the numbers representing the various adjustable resistances become familiar, and their places known, so that the operation of shifting the plugs to get balance is more quickly performed, and the final result read off by a glance at what plugs are out. A modification of the conductor resistance test, when interfered with by earth currents, has been adapted from the Mance method by Mr. Kennelly, and consists in taking pairs of readings with different bridge ratios, and so arranging the electromotive force or resistance in the testing battery circuit that one observation in each pair is taken with the strength of current to line twice that in the other. By this means, as in the Mance method, the earth current interference is neutralised, only one direction of current to line is used, and the balance is adjusted to true zero, while the formula is very simple to work from.

Further, in determining the insulation resistance of a working cable, acquaintance is made with the electrification effect by which the insulating material appears to increase in resistance as the current is kept on. The earth current has again to be noticed and allowed for by adding or subtracting the amount of its deflection from that due to the cable, while some calculations in shunts generally come in, and temperature corrections for the resistance of the galvanometer. In these tests, dexterity is acquired in the use of the galvanometer short-circuit key, in bringing the spot of light up to its deflection or back to zero again, without a number of inconvenient oscillations, and in preventing the strong momentary currents due to charge and discharge, or the continuous currents due to want of balance on the bridge from passing through the galvanometer. The use of this key in false zero testing is most important. In bridge work, in order to see whether a given balance is correct to false zero, the galvanometer is short-circuited for an instant while the testing current is cut off, and the cable discharge dissipated, and then thrown into circuit again by the key to observe the position of false zero. More is done by tapping this key with the fingers than anything else, and the necessary dexterity is only acquired after practice in watching the effect made upon the movements of the spot of light.

In capacity tests the standard of comparison rarely exceeds one microfarad, and is frequently made in boxes of one-third of a microfarad, or about equal to one mile of cable. With a

Digitized by Google

few hundred miles of cable on, therefore, there is a great disparity between the amounts of capacity to be compared, and the measurement by simple comparison of discharge is open to objection. With momentary currents through the galvanometer, the simple ratio of the multiplying power of the shunt is not strictly true, because the current through the galvanometer is choked by the self-induction of the coils, while the current through the shunt passes with nothing more than the ohmic resistance of the shunt coils to oppose it, these, like all resistance coils, being wound non-inductively. On the other hand, without a shunt to reduce the discharge throw of the cable within comparable limits, the two readings are inconveniently far apart on the scale, and any slight errors in observation affect the result considerably. The method of Thomson, by which the two discharges are mixed and neutralised, leaving no current, when balanced, to pass through the galvanometer, is greatly in favour, both on account of its accurateness in measuring widely differing capacities and ease of manipulation. Either a Lambert or Saunders key is usually supplied to stations and ships for this test, by means of which the consecutive operations of charging separately, discharging together, and connecting to the galvanometer are performed, while the resistance on one side is simply adjusted by hand till balance is attained.

In all electrical tests it is well to notice what degree of accuracy can be attained. This depends partly upon the observations, whether of deflection or zero balancing methods, and partly upon the arithmetical calculations, which have to be made to arrive at the final result. In bridge tests it should be observed what are the limits between which balance can be maintained, and then the arithmetical calculation gone through again with the object of seeing how much the final result is altered by an error in observation of the amount determined by the above limits. Frequently this can be seen, as regards the calculation, by simple inspection of the algebraical form of the formula by which the test is worked out, some formula allowing much more margin for errors in observation than others. The smallness of the limits between which a balance can be maintained, or, in other words, the sensitiveness of an observation, depends more or less on the relation between the resistances of all the pieces of apparatus employed in the test, and also, as regards the galvanometer, upon the nature of the suspension, the number of turns of wire in the coil, and the position of the controlling magnet.

As reliability and dexterity are acquired in these ordinary tests, opportunities will more readily be found for assisting in the localisation tests when a fault or break occurs. There is no need, however, to wait for the appearance of a fault in the line in order to obtain practice. With a little sea water, a foot or two of cable core, and a bit of galvanised iron wire or plate, an artificial fault can be set up, which, together with some resistance coils, affords excellent practice in localisation tests. There is a distinct advantage in practising with faults of this kind, for with the artificial fault contained in a glass vessel, the process of deposition of chloride of copper upon the exposed part of the conductor, with the copper current, and the rate of evolution of gas with the zinc current can be closely watched, and a correct idea formed of what actually goes on at the fault in a submerged cable when under the action of testing currents. Moreover, the polarisation effect at the fault, that is, the electromotive force set up in opposition to the testing current, and in proportion to its strength, can be better observed in an artificial fault, because there is no cable discharge to prevent the observation of the false zero immediately after the circuit of the testing battery is broken. The rapid fall in the electromotive force of polarisation is thus more easily observed, and the importance better understood of working to a false zero, approximating as closely as possible to that value of this electro-motive force (or the current caused by it) which is in action during the application of the testing battery.

Faults of high resistance are sometimes localised by what are called fall of potential tests, the *fall* referring to the potential distributed along the cable when charged by a battery. In Mr. Clark's method the difference of potential between the ends of a resistance added to the line is measured at one end, while as nearly as possible at the same instant the potential at the other end is measured, that end being free, and, therefore, having the same potential as the fault. The potentials are measured either by an electrometer, a galvanometer and condenser, or a galvanometer and high resistance, and the results obtained at each end, compared by reference to some standard of electromotive force. This method, however, is not so well adapted for a small fault in a long cable, as the proper form of the curve of charge due to uniform leakage along the cable must be taken into account, and a somewhat lengthy correction applied. A successful departure from ordinary fall of potential tests has been devised by Messrs. Harold Ansell and Julian Young, depending on the electromotive force set up by the fault itself. When the fault is large, and its potential too low to obtain a satisfactory reading, a positive current can be put to line for a few minutes to seal it up and raise the potential, the test being independent of the actual resistance offered by the fault.

(To be continued.)

ELECTRICAL EXHIBITION AT THE CRYSTAL PALACE.

The visit of the Lord Mayor on Saturday last to the Electrical Exhibition at the Crystal Palace was the occasion of a considerable gathering, both of the exhibitors and of others interested in electric lighting. Almost all the strictly electrical exhibits were completed; but those of some of the upholstering and furnishing exhibitors, who always put in an appearance on these occasions, were still in a rather backward state. The machine-room is well worth a visit by every electrical engineer; and no mechanical engineer should lose such an excellent opportunity of inspecting, not only dynamos, but the engines which are used for driving them.

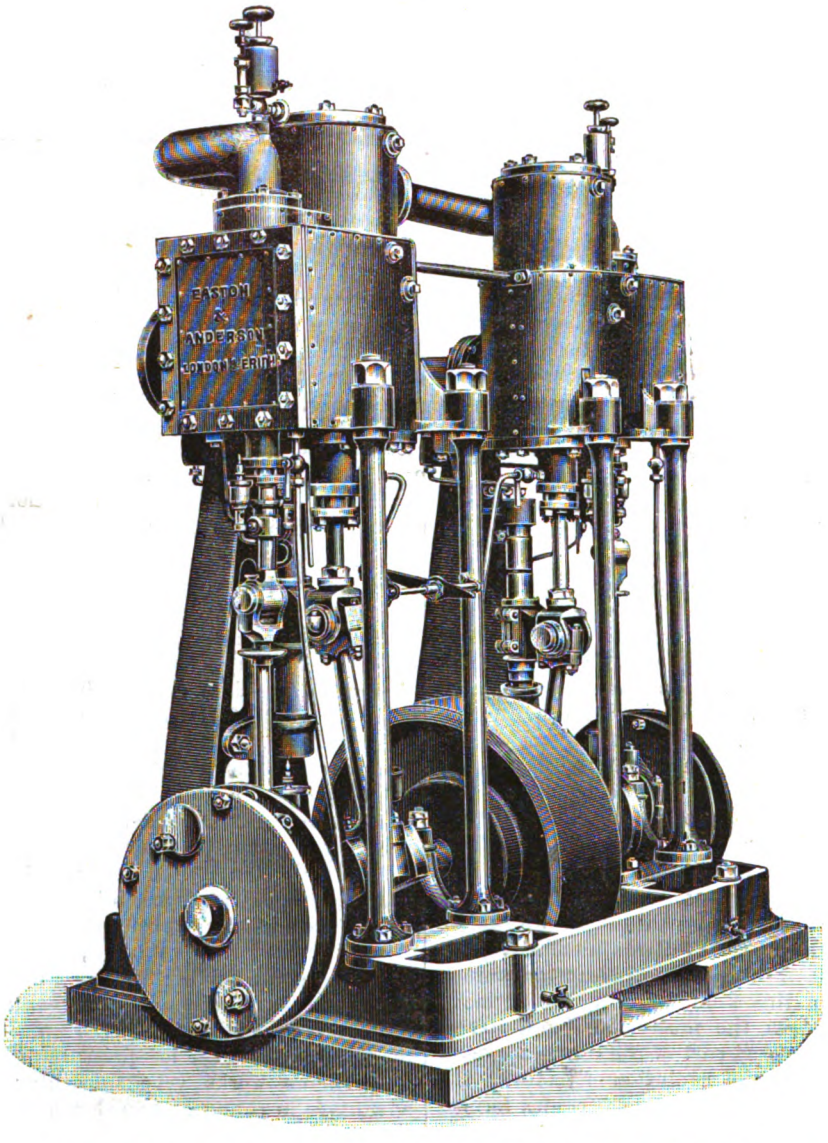
It is to be noticed that a particular type of engine has become very popular for both direct-driven and belt-driven dynamos. It is by no means a new pattern. We refer to an inverted double-acting engine, with a cast-iron standard, something like one-half of the standard of the old steam-hammer type, but instead of the second half massive wrought-iron pillars are provided. While these are excellently adapted for taking the longitudinal stress, they present the great advantage that the engine has a front and a back, and that the front is easily accessible. The old-fashioned table engine, in which four or more wrought-iron, or even cast-iron pillars, supported a casting which was dignified by the name of entablature, was thoroughly accessible, but the columns alone presented too little lateral stiffness. Excellent examples of this type are to be found in the Raworth engines, which are driving Brush machinery, the largest size giving 250 H.P. at 167 revolutions, and also in the large Davey Paxman engine driving the Kapp multipolar dynamo, to which we have already referred. This engine is triple expansion, the high-pressure cylinder being 12in. in diameter, the intermediate 18¾in., and the low-pressure 30in., with an 18in. stroke. The engine works very smoothly; but we fail to see any advantage in running at so slow a speed as 130 revolutions per minute.

The latest makers who have adopted this class is the well known firm of Easton and Anderson, who exhibit one of their Stoker's patent high-speed engines. This engine, now running at Messrs. Easton and Anderson's stand, No. 42, consists of two tandem compound engines, side by side, working on to a common crankshaft, with cranks opposite, and having a fly wheel between them. The engines are single-acting, the cylinders being 6in. diameter and 10½in. diameter high and low pressures respectively, by 8in. stroke. It will develop at 100lb. steam pressure about 60 I.H.P., with 450 revolutions per minute, non-condensing; but is constructed to work with more pressure if required; in fact, it is working with 120lb. at the Crystal Palace under a light load on a small "Whitehall" dynamo. The principal features of it are—carefully-studied arrangement of the steam distribution in the cylinders, whereby the maximum of economy is obtained, and the valves are so arranged that the cut-off can be varied by means of Turner-

Digitized by Google

Hartnell or other crankshaft governors, as shown in the illustration, or it may be used with the ordinary eccentrics, and an ordinary governor such as the Pickering, with which it is now running at the Crystal Palace.

The other points to which special attention has been given are—the accessibility of all parts for ready inspection and removal; stiffness of the whole structure; lightness of the moving parts, whereby, together with the steam distribution, quiet running is assured; efficient lubrication of all parts, so that every bearing and surface can be efficiently oiled during the longest runs, without the necessity of stopping the engine. Noteworthy features in this engine are its high piston speed, and the use of pillar guides. These are not new; but we think might oftener be adopted with advantage. The old-fashioned slipper guide, with its planed surfaces, has been replaced by a cylindrical guide in several gas engines and steam engines, the surface being shaped while the cylinder is being bored; but adjustment for wear is rather troublesome. The pillar guides in this engine are lubricated by a sheet brass sleeve carried by the crosshead, and cut with many longitudinal slits. This dips into oil at every stroke. As running at the Crystal Palace, the engine is driving a dynamo by means of a belt, but it is equally well adapted for coupling direct on to a dynamo.



Stoker's Patent High-Speed Engine. (Made by Messrs. Easton & Anderson.)

The massive Siemens dynamo is erected, but does not look quite so large as it did when the pieces were lying about. Perhaps the most prominent machine in the room is the 130-unit Crompton dynamo, coupled to a Willans engine. This bears the card, "Sold to the Notting Hill Electric Supply Company," as if the secretary of that Company had happened to pass by the stand and made the purchase on the spot. The Crompton exhibit includes not only steam-engines, but also a good show of Crompton-Howell accumulators, and a very complete demonstration of the method of laying mains on the Crompton conduit system. Some yards of main have actually been laid in a concrete conduit, and a large grave has been dug in the space representing the roadway, to allow visitors to descend to the level of the conduit, and to inspect it through side holes which open into the grave. It may be noticed that almost every dynamo in the Exhibition is provided with gauze brushes; and we observed that the Taunton dynamos are provided with screw-feed brush-holders, allowing an adjustment to be made without slackening or tightening the nut holding the brush. An ingenious arrangement for preventing waste of the butt end of brushes has been invented by Mr. Dowsing, who has adapted the well-known candle "save-all" system. We hope on another occasion to make a still more careful examination of the dynamos; but up to the present we have failed to discover much that has not already been described in these columns.

Steam is supplied to the engines by a set of eight steel locomotive boilers, made by Davey Paxman. These are independently connected to a steel steam receiver, and the steam piping throughout the machine-room is very well arranged. A large number of gas engines are running at the south end

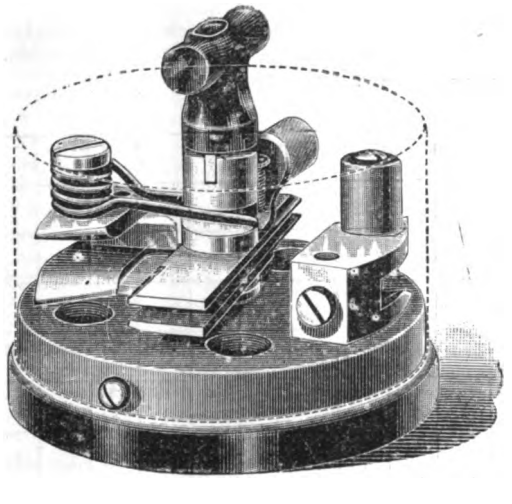
Digitized by Google

of the machine room; but there is either very little to be said about gas engines, or the attendants are singularly uncommunicative.

A large wire screen has been erected across the nave, at the north end of the Exhibition, on which a number of devices in glow-lamps (forming advertisements of the Edison Swan Company) are arranged and are switched in in succession during the evening.

The one department in which novelties are always to be found, but which is singularly destitute of originality, is that of artistic fittings. A very extensive display of these is to be found at the Crystal Palace; and all those who are intending to fit their houses with the electric light should certainly pay a visit to the numerous stalls and furnished rooms. We hesitate to criticise the art fittings, since they are only incidentally connected with electric lighting, and ought to be treated upon artistic grounds. We suppose that we are very hard to please; but we could find very little that was really satisfactory, except some good plain iron work at the stand of Messrs. Shirley and Co. This firm also shows some very good and simple examples of artistic iron work. There is one notable exception, of a single pendant with a set of appropriate brackets, which surpasses anything else in the Exhibition, and this we hope to illustrate on a future occasion.

The gallery of the south nave is fitted with a number of rooms, most of which are overloaded with decorations and ornaments. In those of Messrs. H. J. Cooper and Co. it is rather



difficult to find the electric fittings at all. These fittings consist of some good work of Messrs. Faraday and Son; but the use of electrically fitted candlesticks upon a dining-room table seems to be a confession of weakness, and reveals a sad want of imagination. Cupids, hung up like game by the heel, are considered by some to be a very artistic and novel means of suspending a glow lamp. Frank Giles has a room fitted with some very fine oak carving and another decorated in the French style; but these are lit almost entirely by imitation candles, with small flame-shaped glow-lamps. The method of lighting is, in our opinion, about as inartistic as it is possible to conceive. There is no doubt a difficulty in lighting a room decorated in the French style with anything but candelabra, and given candelabra it requires a little courage to put anything else than a candle in them. An utterly impossible room is shown by Messrs. Allen and Mannock. The ceiling is covered with quilted satin, and the whole is very like an elaborate *bon bon* box turned outside in. In the south nave there are several stands of fittings, most of which are merely hung up side by side as in a show-room, without any attempt to represent a habitable apartment.

No article on an Electrical Exhibition would be complete without some blocks taken out of price lists and catalogues. We therefore illustrate a switch made by Messrs. Dorman and Smith, which is provided with Siemens patent carbon breaks. It will be seen that the switch itself consists of two metal plates, which pass between splayed contact jaws, making a firm spring contact. One of these jaws carries a carbon block, and another is mounted upon the working part of the switch. The mechanism is arranged so that contact is finally broken by the separation of these carbon blocks. Messrs. Dorman and Smith occupy the uncommon position of confining themselves to the sale of their own manufactures, and do not fill up their catalogue with engines, boilers, dynamos, and multifarious sundries of other makers.

The management of the Crystal Palace is to be congratulated upon the fine display of machinery apparatus and accessories, which are sure to attract many visitors; but they are fettered in an unfortunate manner by various contracts, which inconvenience both exhibitors and visitors in a way which they must often regret. No exhibitor can photograph his stall except by stealth, because of a photographic contract; the printing and publishing contractors look sharp after their pound of flesh, and it is a wonder that they do not insist on printing all the exhibitors' circulars. Of the refreshments and restaurant department it is only necessary to say that it is as bad as ever.

THE METRIC SYSTEM.

In the course of some interesting articles in the *Engineering Magazine* of New York, in which Mr. Coleman Sellers is trying to demonstrate "American Supremacy in Applied Mechanics," he makes the following observations on the use of the metric system in engineering.

The much-traduced metrology of England and America lends itself most happily to standard sizes that can be readily memorised and readily used. This does not come from any particular merit in the English inch, but in the non-use of a purely decimal division of a unit. The inch divided into fourths, eighths, sixteenths, thirty-seconds, and sixty-fourths by successive halvings, permits a graduation of sizes that can be memorised, making shop sizes to vary by a sixteenth of an inch up to one inch or two or three or a quarter of an inch above that size, presenting a memorisable series of sizes that is as natural as the divisions of music.

In countries using the metric system the millimetre is the unit of the machine shop, and an iron rod 1in. in diameter called 25 millimetres, even when it measures $25\frac{4}{10}$ exact, and drills used in the shop for advancing in size by a millimetre, from 4 millimetres to 25, will give more separate dimensions than are really needed. Economy in shop equipment is found in the use of only a limited number of progressive sizes, as each standard dimension requires many separate pieces in all the tools made to that size; even in a modern tool-room, counting all the taps, drills, reamers, gauges, boring tools, turning and planing tools for any one given size, there will be found from 70 to 140 separate and distinct tools to each size. The multiplication of sizes is attended with great cost in stock and on compensating gain.

In practice, the metric nations use the empirical graduations of shop sizes, advancing by two or three millimetres in a series that is not uniform but nearly approximates to the separate gradations in use in rolling the iron turned out by the English rolling-mills, which are scaled to the usual division of an inch, five-eighths, three-fourths, and so on.

The French centimetre may be divided as we divide the inch; but with the new divisions of the centimetre in halves, quarters, eighths and sixteenths, comes the destruction of the decimal system, which, in truth, is of less value when applied to measures and weight than it is in currency, and the intensity with which the British nation holds to its duodecimal system of money and the rapidity with which even the most ignorant use this seemingly complicated currency shows that there is not so much merit even in the decimal system of money to introduce it when a nation must be taught new habits of thought.

Long before the metric system was legalised in America, the present writer readily agreed to its adoption in a large department of the workshops he was then interested in, in order that in doing one particular kind of work which lent itself readily to the metric metrology, the experiment could be tried as to its superiority over that in common use; but with the result of

Digitized by Google

satisfying himself that it was very far from meeting the exaggerated claims made for it by its advocates. The metric system is now legalised in America, and with this legalisation legislative action should end. Let those new branches of trade that are springing up, the new developments of art and science that can use the metric system to advantage, do so. The present condition of metrology with the English-speaking nations adhering to a non-decimal division of the inch with all Russia to back them in it, the time is not come, if it ever will, that this great population should be compelled by legal action to depart from standards and methods that have been accompanied by such surprising advance as has been shown in the nineteenth century. This is the more true when men willing to test the new metric system find it, after more than a quarter of a century's use, less advantageous than has been represented in some branches of applied mechanics. Those only are capable of judging of this matter who have become familiar with both systems to the extent of being able to think in either system of metrology as readily as some men can speak and write several languages.

There are cases in which the metric system can be used universally; in such cases let it be used; let it be taught in the schools, then through the survival of the fittest the truth will be reached. Chemists and electrical engineers should be free to use what is best; while those who are familiar with pounds and ounces should be free to buy and sell with the weights and measures most familiar to each.

ON THE LAW OF HYSTERESIS.*

BY CHAS. PROTEUS STEINMETZ.

In the number 137, of December 17, 1890, of the *Electrical Engineer* I published a short article under the title "Note on the Law of Hysteresis," where I showed that in a set of determinations of the loss of energy due to hysteresis by reversals of magnetism, for different magnetisations, made by Ewing, this loss of energy due to hysteresis can fairly well be expressed by the equation

$$H = \eta B^{1.6},$$

where H is the energy consumed by hysteresis during one magnetic cycle, in ergs per cubic centimetre, B the magnetisation in lines of magnetic force per square centimetre, and η † a numerical coefficient, in this case = ·002.

Considering that even the simple law of magnetism—that is, the dependence of the magnetisation B upon the magneto-motive force F (for instance, in ampere turns per centimetre length of the magnetic circuit)—has until now defied all attempts of mathematical formulation, it appeared a strange feature that the apparently much more intricate phenomenon of hysteresis, or rather of the consumption of energy by hysteresis, should yield to analytical formulation in such a simple way, to be directly proportional to the 1·6th power of the magnetisation. At the same time the coincidence of Ewing's tests with the curve of the 1·6th power was near enough to be considered as something more than a mere incident, but at least as a clue to a law of hysteresis, the more as this law held not only for low and medium magnetisation, but even for very high saturation, without showing any kink at that point where the magnetic characteristic goes over the bend or "knee," and thereby entirely changes its shape, nor any marked tendency of deviation of the extremest observed values from the calculated curve.

In Fig. 1 and Table I., I give from the article referred to, the calculated curve of hysteretic loss, as a drawn line, with Ewing's tests marked as crosses, and in dotted line the curve of magneto-motive force F, corresponding to the different magnetisations, as abscissæ.

In the Table I. :

F = the M.M.F. in absolute units,

B = the magnetisation in lines of magnetic force per square centimetre,

H_{obs} = the observed values, and

$H_{calc.}$ = the calculated values of hysteresis loss in ergs per cubic centimetre,

$H_{calc.} - H_{obs.}$ = the difference between, both in ergs and in percentages.

TABLE I.

F	B	$H_{obs.}$	$H_{calc.}$	$H_{calc.} - H_{obs.}$	$= \%$
1·50	1,974	410	375	+ 35	+8·5
1·95	3,830	1,160	1,082	+ 58	+5·0
2·56	5,950	2,190	2,190	--	—
3·01	7,180	2,940	2,956	- 16	- ·5
3·76	8,790	3,990	4,080	- 90	-2·3
4·96	10,590	5,560	5,510	+ 50	+ ·9
6·62	11,480	6,160	6,260	- 100	-1·7
7·04	11,960	6,590	6,690	- 100	-1·5
26·5	13,700	8,690	8,310	+ 380	+4·4
75·2	15,560	10,040	10,190	- 150	-1·5
				Av: ± 98 =	±2·6

To study more completely this phenomenon of hysteresis, and of the energy consumption caused thereby, I endeavoured to make a number of determinations with different magnet circuits and at different magnetisations.

To be enabled to carry out these experiments, I am highly obliged to Mr. Rudolph Eickemeyer, of Yonkers, N.Y., who, being greatly interested in the laws of the magnetic circuit, and having done considerable work himself in this branch of electrical science, not only put the large facilities of his well-known factory at my disposal, but also guided the experiments with his valuable advice. A part of the instruments used in the tests are of Mr. Eickemeyer's invention and covered by his patents.

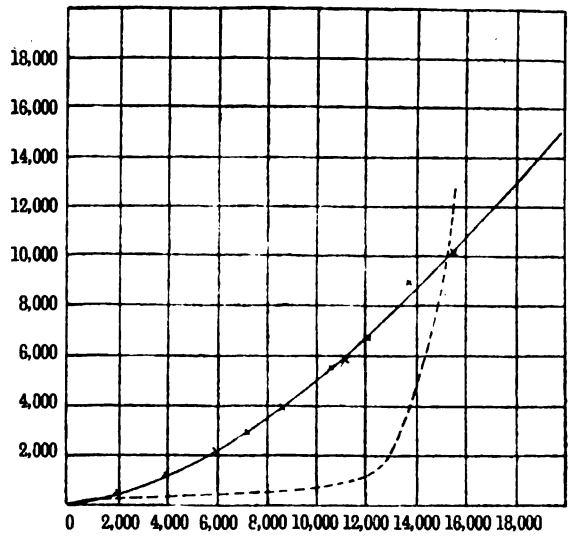


FIG. 1.

To be able to deal, not only with the small amounts of energy which the reversal of magnetism in a tiny bit of iron wire sends through the ballistic galvanometer, but to reduce the determinations to readings of considerable power-values, and where a much greater exactness can be reached, and at the same time to determine the dependence of the hysteretic loss of energy upon the velocity of the magnetic cycles, I decided to use alternating currents, at least as far as this could be done, whereby the determinations of the energy consumed by hysteresis is reduced to a simultaneous wattmeter, voltmeter, ammeter, and speed reading.

At the same time this electro-dynamometer method has the advantage that the magnetic cycle is completed in a steady, continuous motion, while in the ballistic method the magnetic cycle is completed by sudden changes in the magnetisation, which jumps from point to point, to enable the production of the induced current. This feature introduces an error into the ballistic method; for if a magnetic cycle is gone through by sudden changes, a larger amount of energy may be consumed than if the magnetisation varies steadily in harmonic vibration.

Suppose, around a magnetic circuit, an alternating current of n periods per second is sent in c convolutions.

* Abstract of a Paper read before the American Institute of Electrical Engineers, New York, January 19, 1892.

† If any quantity has a right to be called "magnetic resistance," it is this coefficient η; for η is the *coefficient of conversion of magnetic energy into heat*, while as "electric resistance" we define the *coefficient of conversion of electric energy into heat*.

The term generally denoted "magnetic resistance"—that is, the inverse value of magnetic susceptibility—does not deserve this name at all, but is more properly called "reluctance."

Digitized by Google

Let C = the effective strength of the current,

E = the effective E.M.F. induced in the circuit by self-induction, after subtracting the E.M.F.s induced by the self-induction of the instruments,

W = the energy consumed in the circuit, after subtracting the energy consumed by the electric resistance,

Then, l being the length and s the cross-section of the magnetic circuit, all in centimetres, amperes, volts, watts, &c.,

Let $\mathbf{B}$ = the maximum magnetisation in lines of magnetic force per square centimetre,

H = the loss of energy by hysteresis per cycle and cubic centimetre; it is

$$W = l\,s\,n\,H \times 10^{-7};$$

hence

$$H = \frac{W}{l\,s\,n} \times 10^{-4},$$

the hysteretic loss of energy, and

$$E = \sqrt{2}\pi\,s\,\mathbf{B}\,n\,c \times 10^{-8}.$$

hence

$$\mathbf{B} = \frac{E \times 10^{+8}}{\sqrt{2}\pi s n c} \quad (*),$$

the maximum magnetism.

For higher frequencies, 80 to 200 periods per second, the alternating current was derived from a 1 H.P. 50-volt Westinghouse dynamo. This was driven by a 3 H.P. Eickemeyer continuous-current motor. By varying the excitation of the motor field, and varying the E.M.F. supplied to the motor, the speed and therefore the frequency of the alternating current could be varied in wide limits. At the same time, supplied with constant E.M.F., and like all the Eickemeyer motors of unusually small armature reaction, this electromotor kept almost absolutely constant speed under varying load, the more as it never ran with full load.

For low frequencies, this bipolar continuous-current motor was used as a bipolar alternating dynamo, as shown in a patent of Mr. Stephen D. Field. On the continuous-current commutator two sliding rings were mounted and connected with opposite commutator bars. In the ordinary continuous-current brushes a continuous current was sent in, which set the machine in motion as an electromotor, while from the sliding rings by two separate brushes alternating currents were taken off. By varying the E.M.F. supplied to the motor, the E.M.F. of the alternating current was varied, while a variation of the motor field gave the variations of the frequency. The curve of E.M.F. was very nearly a sine-wave, the ratio of maximum E.M.F. to effective E.M.F. found = 1·415, while the sine-wave requires 1·414—that is, exactly the same.

To determine whether the change of the shape of the alternating current by varying load and varying excitation had any influence upon the readings, the variations of the alternating E.M.F. were produced:—

1. By varying the excitation of the field of the Westinghouse dynamo.

2. By running the Westinghouse dynamo fully excited, feeding the secondaries of a bank of converters, feeding from the fine wire coils of these converters the fine wire coils of another bank of converters, and taking current off from the secondaries of these converters, connected from one to six in series.

3. By changing the E.M.F. by means of a Westinghouse converter of variable ratio of transformation.

4. By loading the dynamo when small currents were used for the tests.

But after having found that all these different ways of varying the alternating E.M.F. gave no perceptible difference whatever in the readings, I afterwards used the most convenient way to vary the excitation of the dynamo field, and, where higher E.M.F.'s were needed, to increase the E.M.F. by an interchangeable converter, which gave the ratio:—1: 1, 2, 3, 4, 5.

For the determination of the frequency, a direct-reading speed indicator (horizontal ball governor, acting upon a spring) was used, which was carefully calibrated.

For the electric readings, instruments of the electro-dynamometer type were used, zero reading—that is, the movable coil was carried back by the torsion of a steel spring to zero position.

* This formula holds rigidly only for the sine-wave; but as shown in the following, the currents used in the tests were at least very near sine-waves. Besides, a deviation from the sine shape would not alter the results at all, but only slightly change the coefficient η.

These instruments were specially built for alternating currents, with very low self-induction and low internal resistance, using bifilar German silver wire as additional resistance.

In the ammeter the range of readings was from 3 to 40 ampers the internal resistance = ·011 ω.

The normal inductance (that is, E.M.F. of self-induction induced by one ampere alternating current, flowing through the instrument with a frequency of 100 complete periods per second: = ·045 ω.

In the voltmeter the range of readings was from ·5 volts upwards, but to avoid the necessity of corrections for self-induction, sufficient additional resistance was used to decrease the correction under 1 per cent., and then the lowest readings were from 3 to 6 volts.

The internal resistance of the voltmeter is = 2·5 ω, its normal inductance = 4·12 ω.

In the wattmeter the resistance of the coarse-wire coil (fixed coil) was = ·026 ω, its normal inductance ·073 ω.

The internal resistance of the fine-wire coil was = 25 ω, its normal inductance = ·33 ω.

In most of the readings sufficient additional resistance was used to make the correction for self-induction of the fine-wire coil negligible. Only in a few readings where it exceeded 1 per cent. it was taken in account.

For small currents an Eickemeyer ammeter was used, which, while reading from ·7 to 3 amperes, though built originally for continuous currents, had already been used by me for alternating currents, and had been checked for its constancy of readings several times, and always found to give no perceptible difference in its readings for continuous currents and for alternating currents up to over 200 complete periods per second, the highest frequency I could reach.

Its internal resistance is = 1·1 ω, its normal inductance = 2·03 ω.

Several sets of readings for different frequencies were taken on an old Westinghouse voltmeter converter. The fine-wire coil and one of the 50-volt coils were left open. Into the other coarse-wire coil an alternating current was sent, in series to ammeter and coarse-wire coil of wattmeter, while the voltmeter and the fine-wire coil of the wattmeter were connected in shunt around the whole circuit.

Hence a correction had to be applied for the self-induction of ammeter and coarse-wire coil of the wattmeter and for the resistance of the circuit. Only in very few readings this correction amounted to somewhat more than 10 per cent. Generally it was much smaller.

The instruments were calibrated several times, and their constants found to remain constant.

The speed indicator was calibrated carefully, and its corrections added.

Each reading consisted of an ammeter reading, a voltmeter reading, a wattmeter reading, and a speed reading.

Before and after each set of readings the zero positions of the instruments were determined, and only those sets of readings used where the zero position had remained constant.

Before and after each set of alternating-current readings a continuous current was sent into the circuit and a few readings for different currents taken. Voltmeter and ammeter readings combined gave the resistance of the circuit, and both combined with the wattmeter reading gave a check for the instruments, here being watts = volts × amperes. Only those sets were used again where an entire agreement was found, and with the alternating current first readings with small currents taken, then with large currents, and then again with small currents taken, so that I believe every possible care was exercised to avoid any errors in the tests.

As before said, the first sets of tests were made on the magnetic circuit of a small Westinghouse converter.

The constants of this converter, so far as they are of interest here, are:

Mean length of magnetic circuit, 21cm.

Mean cross-section of magnetic circuit = 43·67cm.^{2}

Hence volume of iron, = 917cm.^{3}

Resistance of secondary coil, = ·2 ω.

Further sets of readings were taken on a magnetic circuit, built up of very thin sheets of iron, alternately 8in. × 1in. and 3in. × 1in., in rectangular shape, very carefully insulated against eddy currents with layers of thin paper between the sheets. On the two long sides two coils of each 50 turns, very coarse wire (3 No. 10 in parallel), were wound and connected in series, thereby giving n = 100 turns of an internal resistance of ·048 ω.

Here the mean length of the magnetic circuit was l = 41cm.

The cross-section, s = 3 784cm.^{2}

The circuit consisted of 58 layers of sheet-iron of the thickness s = ·02577 (*) and the width w = 2·579.

The whole volume of iron was = 155cm.^{3}

The sheet-iron pieces were first freed from scales by dipping into dilute sulphuric acid.

* Calculated from the weight.

Digitized by Google

In one set of tests an open magnetic circuit was used, by leaving the short end pieces (3in. × 1in.) off, and using two piles each of 66 pieces (8in. × 1in.) of the same iron, the same pieces as used in the former closed circuit tests.

In these readings, for the determination of the hysteretic loss, only voltmeter and wattmeter, but no ammeter, were used, and the susceptibility curve determined separately by voltmeter and ammeter.

The calculation of the readings was done in the following way:

After applying the corrections for self-induction of instruments, resistance and speed, the readings were reduced to lines of magnetic force per square centimetre **B** and consumption of energy by hysteresis per magnetic cycle H, in ergs.

Then the results were plotted on cross-section paper, and if any value was found to be very much out of the curve connecting the other values, it was stricken out as evidently erroneous, not considering it worth while to determine whether it was a wrong reading of any one of the instruments or a mistake in the calculation.

Then from the other values of **B** and H, under the supposition that H were proportional to any power x of **B**,

$$H = \eta \mathbf{B}^x$$

this exponent x was determined.

This value x will be seen always to be so near to 1·6 that 1·6 can be considered at least as first approximation to x.

Then, under the assumption

$$x = 1{\cdot}6$$

hence

$$H = \eta \mathbf{B}^{1{\cdot}6}$$

the coefficient η was calculated, and now the equation

$$H = \eta \mathbf{B}^{1{\cdot}6}$$

plotted in a curve, as given in the figures, and the observed values of H drawn in and marked.

From the curve were taken the calculated values of H, corresponding to the observed values of B, the difference $H_{calc} - H_{obs}$ determined, and expressed in per cents of H_{calc}.

These values are given in the tables and shown in the curves.

I.—Magnetic Circuit of the Westinghouse Converter.

In the following Table the results are given of many observations taken at different frequencies, n, and induction densities **B**. In this Table the numbers in the third column denote the power of **B** which is most nearly proportional to the hysteresis loss H, and the next column gives the corresponding coefficient η. The last

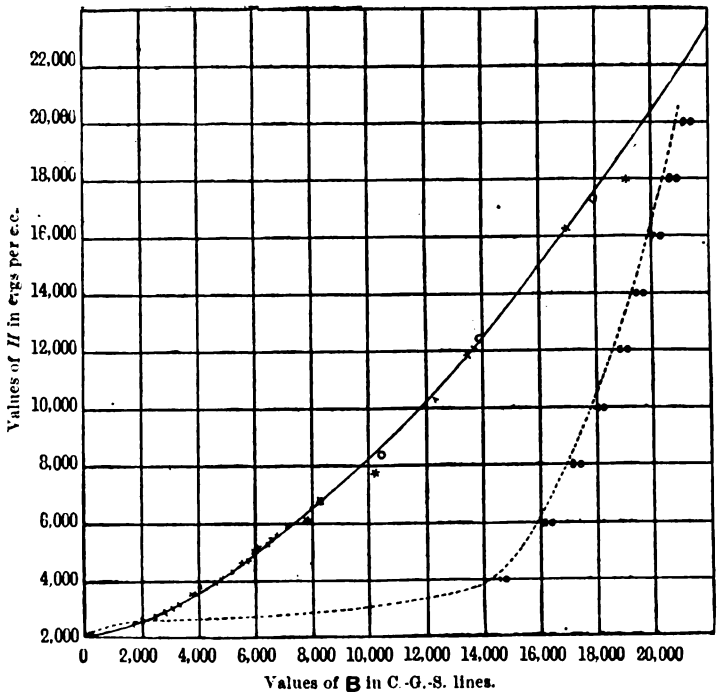

Fig. 2.

column indicates the agreement of the observed and calculated values, as it is the average percentage difference between them.

1	...	$n=28$	...	4 readings:	$x=1{\cdot}6111$	...	$\eta=\cdot002410$	... 2·3 %
2	...	36	...	5 „	1·6476	...	·02315	... 4·4 „
3	...	137	...	10 „	1·5887	...	·002438	... 2·0 „
4	...	205	...	18 „	1·6012	...	·002434	... 2·7 „

Therefrom we derive the average, by giving to each value as weight the number of readings, where it is based upon:

$$x = 1{\cdot}60513 \sim 1{\cdot}6$$

$$\eta = \cdot0024164.$$

Hence,

$$H = \cdot0024164\, \mathbf{B}^{1{\cdot}6}.$$

This curve is used for calculating the values given as H_{calc}, and is plotted in Fig. 2 in drawn line.

The observed values of H are drawn in Fig. 2:—

1. For $n=28$ with the mark o
2. „ 36 „ „ *
3. „ 137 „ „ v
4. „ 205 „ „ +

The magnetic characteristic is drawn in dotted lines, and the numbers on it denote the values of the magneto-motive force F in ampere turns per centimetre length.

From this curve of hysteretic loss

$$H = \cdot0024164\, \mathbf{B}^{1{\cdot}6}$$

we derive the values:

Table II. (6.)

Open Magnetic Circuit.

$n=138$ 8 readings: $x=1{\cdot}6040$ $\eta={\cdot}00393$ 3·4 per cent.

Herefrom it seems that the consumption of energy by hysteresis per magnetic cycle increases with increasing frequency—that is, with increasing velocity of the magnetic change.

The three values of three coefficients of hysteresis for closed circuit in their dependence upon the frequency n, can be expressed by the *empirical* formula:

$$\eta=({\cdot}0017+{\cdot}000016\,n-{\cdot}00000003\,n^2).$$

To compare the values of hysteretic loss for different frequencies, in Fig. 3 the curve of hysteretic loss for $n=100$ complete periods per second is plotted, giving:

$$\eta_{100}={\cdot}003;$$

hence,

$$H={\cdot}003\,\mathsf{B}^{1{\cdot}6},$$

and the observed values of H are not directly drawn in, but the observed values of H multiplied with the factor:

$$\frac{\eta_{100}}{\eta\,\text{obs.}},$$

to compare the different frequencies with each other.

These values are plotted for:

$n=$ 85 with the mark Y
138 ,, ,, + } Closed magnetic circuit.
205 ,, ,, *
$n=138$ with the mark O; Open magnetic circuit.

From this curve of hysteretic loss,

$$H={\cdot}003\,\mathsf{B}^{1{\cdot}6},$$

we derive the values, for the frequency of $n=100$ complete periods per second.

TABLE III.

B.	H.	B.	H.
1,000	190	13,000	11,460
2,000	570	14,000	12,900
3,000	1,100	15,000	14,430
4,000	1,740	16,000	15,990
5,000	2,490	17,000	17,610
6,000	3,330	18,000	19,290
7,000	4,260	19,000	21,060
8,000	5,280	20,000	22,830
9,000	6,360	25,000	32,640
10,000	7,530	30,000	43,680
11,000	8,790	35,000	55,950
12,000	10,080	40,000	69,270

Especially noteworthy is the last set of readings, on open magnetic circuit, in so far as it proves the fallacy of the general opinion that the hysteretic loss of energy in the iron is smaller in the open magnetic circuit than in the closed circuit.

For the coefficient of hysteresis observed on open magnetic circuit

$$\eta={\cdot}00393$$

is even greater than that for closed magnetic circuit,

$$\eta={\cdot}00335.$$

But this discrepancy is easily explained by the fact that in the closed magnetic circuit the magnetisation is nearly uniform throughout the whole iron. But in the open magnetic circuit the magnetic field intensity differs considerably from point to point, being a maximum in the middle of the magnetising coils, a minimum at the ends of the iron sheets. Now, the values of B given in the table are the average values of the magnetisation, and the values H the average values of hysteretic loss. But the average value of the 1·6th powers of different quantities B is larger than the 1·6th power of the average value of B.

For instance, in a cubic cm. of iron magnetised to $\mathsf{B}=12{,}000$ is $H=10{,}080$; in a cubic cm. of iron magnetised to $\mathsf{B}=6{,}000$ is $H=3{,}330$; hence of these 2 cubic centimetres the average magnetisation is

$$\mathsf{B}=9{,}000,\text{ and the average } H=6{,}705\text{ ergs},$$

but to $\mathsf{B}=9{,}000$ corresponds $H=6{,}360$ ergs; that is, about 5 per cent. less, and the difference becomes still greater, if the values B differ still more.

Taking this into account, it seems that the loss of energy due to hysteresis depends only upon the intensity of magnetisation, and, perhaps, upon the frequency, but is independent of open or closed magnetic circuit, as is to be expected.

(To be continued.)

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES, F.R.S.

On commencing his third lecture Prof. Forbes alluded to the work and experiments of Mr. Nikola Tesla. The "practical man," said Prof. Forbes, had asked in a technical journal what it would all lead to. His advice to the "practical man" was to leave Mr. Nikola Tesla's experiments alone; the so-called "practical man" could hardly appreciate the value of such work. He had hoped the time was now passed for those who had formerly done so to arrogate to themselves the title of "practical man." Such an arrogation showed great self-sufficiency, for the title was the highest possible; even our greatest men did not speak of themselves as "practical men." As a rule the title was assumed by those who could use their hands, but not their heads.

To engineers and natural philosophers Mr. Nikola Tesla's work was full of promise. The engineer saw great difficulties which had been in his way completely explained and partially removed. We now saw our way to producing a most pleasing light by means almost in a practical shape. The natural philosopher had had explained to him a vast number of experiments which puzzled him. Mr. Nikola Tesla triumphed as the natural philosopher to-day, to-morrow he would triumph as the engineer. To the natural philosopher the puzzling alteration in the capacity of the air condenser was now made clear. During the Lauffen-Frankfort transmission experiments a curious light was given off by the wires, and they were at a loss to account for it or to cure it. Mr. Tesla had given us the explanation and the cure. The value of oil as an insulator was indeed known before, but we had not realised its enormous importance.

Returning for a moment to the question of mains, the Siemens type of cable was, Prof. Forbes remarked, a good one in many respects. For feeders it was admirable, but, owing to the necessity for a special junction-box wherever the main was tapped, its cost was considerable when used as a distributing main.

Coming next to the question of Power, as apart from Light, Prof. Forbes said the subject could be divided into two totally different headings, viz., Transmission and Distribution. For instance, in the electrical utilisation of the Falls of Niagara, about which there had been much talk, the great problem was one of *transmission*. The *distribution* of the transmitted power through, say, the town of Buffalo 30 miles distant, was not of such enormous importance. At Clerkenwell, on the other hand, where there were a large number of small motors at work, the question of *distribution* became paramount. No place could be more suitable than Clerkenwell for putting down a large power station.

Whenever we were transmitting power to great distances high pressures became imperative, whatever system we employed; but an engineer never used a higher pressure than was absolutely necessary. In 1881 Sir William Thomson laid down his well-known general rule as to the most economical conductor to be used in any given case. This law was to the effect that the interest on the capital invested in copper should be equal to the cost of the energy wasted in it. In March, 1886, Prof. Ayrton read a paper before the Institution of Electrical Engineers, in which he endeavoured to show that Sir William Thomson's solution of the most economical section to give a conductor was quite inapplicable in a variety of cases connected with the electric transmission of power. Prof. Ayrton urged that, if a given amount of power had to be furnished at the end of a line with a given difference of potential at the dynamo terminals, the greatest economy was obtained not by keeping the current-density constant, but by making it diminish as the length of line became greater. As a matter of fact, all that Prof. Ayrton's mathematics went to show was that the further the distance the greater the cost of copper, and therefore the greater the cost of the energy. This was the whole secret of the mare's nest that Prof. Ayrton thought he had found in Sir William Thomson's argument. The only real practical way of applying the law was to gradually arrive at the most economical conductor by working out the problem for different current-densities.

In the transmission of powers to great distances were we to use continuous or alternating currents? Two years ago, if this question had been asked, nine-tenths of us would have answered that nothing was available except the continuous system. Indeed, the engineers who advised the Niagara Syndicate were on the verge of passing a resolution to the effect that alternating currents were out of the question. He did not desire, however, to under-value the continuous current system. MM. Thury, at Geneva, had erected both at Genoa and Geneva three continuous-current 2,000-volt generators, coupled in series. The difficulties of insulation connected with a physical junction with the source of power had been overcome by the use of Raffard couplings.

Looking at the numerous schemes in progress for providing

* Abstract of Cantor Lecture II., 3, delivered before the Society of Arts February 8, 1892.

Digitized by Google

London with electric railways, it was worth while to consider the use of alternate currents in this connection. In tubular railways, such as proposed, the conductor expenses were solely in the conductor itself, the cost of erecting being in this case small, so that if alternate currents of high pressure were employed we had the total possible gain. Consequently, the adoption of alternate currents was not out of the question.

If we used ordinary continuous-current motors on alternating circuits the field-magnet must be laminated, and the frequency must be low. It was quite possible that if the use of alternate currents on a railway were decided upon at the present moment, low frequencies, and, suitably modified, continuous-current motors would be the best to recommend, owing to the high initial torque of such motors; although, such was the rate of progress, in a few months the aspect of affairs might possibly be quite different.

A type of motor which had attracted much attention was the synchronising alternate-current motor. It was simply the generator worked as a receiver. The synchronising motor had greatly puzzled the "practical man," to whom it was a mystery why some kept well in step and why some did not. A complete explanation was given by Dr. Hopkinson in a Lecture delivered before the Institution of Civil Engineers in 1883. But the drift of his arguments was somewhat misunderstood, and people set to work to put as much iron in the armature as was possible. The astonishment was, therefore, great when Mr. Mordey read his Paper, in which he showed that his alternator with no iron in the armature at all, and very little self-induction, worked as a motor most admirably. The puzzle was complete when comparison was made between Siemens or Ferranti machines and those of Mr. Mordey. The reason for the difference in the behaviour of those machines was simply that the power which was given to an alternating motor pulsated, so that momentum was required to get over dead centres. Now, the Mordey alternator had enormous momentum, owing to the fact that its heavy field-magnets revolved, and the Ferranti alternator only required a heavy flywheel to make it run as well as its rival.

In connection with the Niagara scheme he had recommended synchronising alternate-current machines, the Mordey being specially mentioned. It was proposed to transmit at 10,000 volts, and to transform down to 2,000 volts, and distribute to large synchronising motors in factories. For smaller motors it was proposed to couple synchronising machines to continuous-current dynamos and distribute to the usual type of continuous-current motors.

If we placed two dynamos on the same shaft at one end of the line, and used two similarly situated motors at the far end, and arranged matters so that one dynamo gave the maximum current, while the other gave the minimum, we had an arrangement exactly analogous to that adopted in locomotives, and one which contained the elements of the "rotating phase-system.

Prof. Forbes then explained the principle of the "rotating phase" system by aid of a diagram. There was not the slightest doubt that it was a most effective method of transmitting and distributing power. In addition to the elasticity of the ordinary alternate-current system, we had the enormous advantage that the motors had considerable torque on starting. A small 1 H.P. "rotating phase" motor had been tested by him with the following results:—Current was taken from the mains of the Westminster Company to a continuous-current motor driving an alternator which supplied current to the "rotating phase" motor, which drove a continuous-current dynamo feeding a bank of lamps. The "rotating phase" motor ran at 1,380 revolutions. On starting there was a pull of 40lb. on the 5in. pulley, which at top speed would mean 4 H.P.

TELEGRAPHIC AND TELEPHONIC COAST COMMUNICATION.

At the annual meeting of the Chamber of Shipping of the United Kingdom, held on Wednesday, Mr. Wm. Millburn, jun., the newly-elected President for the year, referred in his opening address to the question of telegraphic communication with lighthouses, lightships, and coastguard stations. He said the carrying out of such a proposal was of national importance, and would be a step forward in the interest of humanity, and as such was entitled to and would doubtless receive the fullest sympathy and support from shipowners. It was a scheme, however, which unfortunately was not to be carried out so easily as it looked. The physical difficulties were greater than at first sight appeared. Many of the lighthouses were situated on a ledge of rocks, and between them and the mainland the bottom was of the same description, with the sea at times breaking heavily upon it, so that no cable could stand for any length of time; and this would probably mean that these rocks would have to be tunnelled, and the cables carried by that means. Again, in the case of lightships, the danger to the cable by vessels anchoring and breaking or damaging it, would have to be guarded against, so that the cost must necessarily be a very serious one; and in dealing with the matter, shipowners would have to be careful that this cost should not be added to their already heavy burdens.

Col. Hill, M.P. (on behalf of the Cardiff Shipowners' Association), moved, "That, in the opinion of this Chamber, it is needful, for the preservation of life, that the lighthouses, lightships, and coastguard stations should be placed in telegraphic communication with each other and the general telegraphic system of the country where practicable." He said he was very pleased to move the resolution, because he had taken a great deal of interest in this important question, in his position as President of the Associated Chambers of Commerce. There was an immense amount of shipping round our coasts, and it was their duty as shipowners to do all in their power to look after the safety of the crews who navigated their ships. The British coasts were well-lighted and well-buoyed; but they were subject to fogs, and accidents sometimes occurred in clear weather as well as in thick. If they wanted to save life and property time was the very essence of success. If a ship got ashore it was of the utmost importance that communication with land should be made with as little delay as possible, so that the necessary life-saving apparatus might be forthcoming. He referred to wrecks, some recent and others which had occurred years ago, where the crews and passengers would of a certainty have been rescued if there had been telegraphic communication between lightships and lighthouses and the land. The question was becoming one of great public interest. It was being taken up by the press. In consequence of the numerous interests involved—the Board of Admiralty, the Post Office, and other departments—the Associated Chambers of Commerce some time ago asked the Prime Minister to receive a deputation on the subject. The Premier, however, thought it was a matter which concerned the Board of Trade. They went to the Board of Trade, and met with a very sympathetic reception from Sir Michael Hicks-Beach, who, however, said that although some experiments for saving life by telegraphic communication with the shore had been only moderately successful, and that further experiments should be made, the Board of Trade could not pay the expense. The Mercantile Marine had funds, and if those who had charge of that fund were willing to spend some of it in these experiments, Sir Michael was quite agreed that it should be done. He (Colonel Hill) was sorry to say the Council of the Mercantile Marine had not seen their way to an expenditure of their funds on the proposed experiments. He had no doubt that public opinion would eventually insist upon the expenses being borne by the National Exchequer. It was unfair that the shipping interest should be taxed with the whole cost of saving life round the coasts. He might mention that the Associated Chambers of Commerce had memorialised Lord Salisbury again, with the result that his lordship had expressed the intention of applying for the appointment of a Select Committee at an early date to investigate the matter. He (Col. Hill) did not see why we should be behind other nations in matters of this kind. He hoped the Chamber of Shipping would take the most active steps in pushing forward this matter.

Mr. John Williamson thought there ought to be no difficulty with regard to lighthouses and coastguard stations; but there were difficulties with regard to lightships, especially when the wires had to pass over rocks. Experiments had been tried on one or two occasions at the Fastnet, but owing to the continuous breaking of the waves no communication could be maintained. Similar difficulties had been experienced in other places. But, after all, there was no reason why a Parliamentary Committee should not be appointed to inquire thoroughly into the matter.

Colonel Hill consented to add the words "or telephonic communication" to his resolution, and it was carried unanimously.

At the annual banquet the same evening, at the Hotel Métropole, Sir Michael Hicks-Beach, in the course of his speech, in answer to the toast of "Her Majesty's Ministers," made the following remarks with regard to coast communication:—

"There is one subject on which I wish to say a few words to you to-night, because I understand it forms an important part in your deliberations to-day. It is the proposal for establishing electrical communication between lighthouses and lightships on our coasts and our telegraph stations inland. It seems to me that in almost all matters connected with shipping there is a tendency to exaggeration. I think there is a little tendency to exaggeration on the part of not a few who have written and spoken on this subject. In the first place, I think it is absurd to suggest that such communication could be established with all the lighthouses and lightships round our coasts for the sum of £100,000, or anything like it. Perhaps I may say that I have taken some steps to endeavour to ascertain the fact by furnishing the Post Office authorities with a statement of the distances between existing lighthouses and lightships and the nearest telegraph stations, and asking them to give

Digitized by Google

an estimate of the probable cost of supplying communication. Secondly, some persons have suggested that such communication would be valuable in case of war for the defence of our coasts. My right hon. friend, the Secretary to the Admiralty, could speak on that subject with greater authority than I can, but I think he will support what I am going to say. If the Eddystone lighthouse, for instance, were to give warning to Plymouth of the approach of a French cruiser in the unhappy event of war between this country and France, that French cruiser, looking to the history of past wars, would be justified in blowing the lighthouse out of existence. That must be a material point in the consideration of this question. Thirdly, it has been suggested- or, perhaps, it is in theminds of some persons—that our lighthouse-keepers and our lightship-keepers might be utilised to perform the work which is now performed by Lloyd's signal stations for commercial purposes. I am glad you do not support that suggestion, because the lighthouse authorities are unanimously of opinion that the keepers have quite enough to do at present in securing the efficiency of their lights and fog-signals, and that it would be impossible to impose upon them any additional duties of this kind. We must look at this matter solely, I would venture to say, with regard to the saving of life in case of wrecks, and we must dismiss from our minds the idea that if every lightship and lighthouse were connected by telegraph now all loss of life on our coast could possibly be avoided. An instance has been suggested to me only this evening by the chairman—the case of the Enterkin at the mouth of the Thames. I have inquired into the matter, and, as you know, a lighthouse was close to the spot where the wreck took place. I have ascertained beyond doubt that it would have been absolutely impossible, if there had been telegraphic communication between that lighthouse and the shore, for assistance to have reached the wreck from the shore in time to rescue the people who were drowning. The people were drowned within an hour of the time of the grounding of the ship, and no help could have reached them in less than three hours, But I do think, gentlemen, that something ought to be done in this matter. I do think that lives are lost now which might be saved if this communication existed in more places than it does. I do not think that you, as a Chamber of Shipping, although I do not agree with you in the desire to transfer the cost of maintaining the lighthouse service from the light dues to the general taxpayer, were justified in stating that this, at any rate, might be a national service and paid for by national funds; and I am convinced that this country will not grudge a very considerable expenditure in the effort to save life, especially in the effort to save life at sea, when a fair and reasonable inquiry has been made as to how that expenditure may be most profitably incurred. We shall propose to Parliament to make that inquiry, in order that something may be done, and in that I hope and believe we have the full sympathy of the Chamber of Shipping. All I would say further on this point is, that it is our duty as a Government, and as responsible to the taxpayers of this country, to take care that the question is justly and properly dealt with, and that, at the same time, it is dealt with in the way that becomes a rich country interested beyond any other country in its mercantile marine, and that does so much by voluntary exertions for the saving of life at sea."

BERLINER'S "ELECTRODES."

In the New York *Electrical Engineer* of January 20th, Mr. Barrett discusses the question of how far the Cuttriss helical carbon spring telephone transmitter (*The Electrician*, January 8th, p. 257) is new and outside the Berliner patent, recently issued by the United States Patent Office. It is first of all pointed out, as was done in our issue of January 15th by Mr. Campbell Swinton, that Edison devised a practically similar device in 1877, the material of the spiral not, however, being specifically mentioned. The question, "What are Electrodes in a Microphone Transmitter?" is next discussed. In the ordinary use of the word, "electrode" conveys decisively the idea of the separation, or at least the separability, of the two terminals of a metallic electrical circuit. Electrodes in constant contact with each other are technically an anomaly. But a special appropriation of the term has been made in Berliner's patent to a matter not within its strict technical acceptance, and a sufficiently intelligible definition for the purposes of the patent is given in the specifications of the patent itself, so that in all discussions of Berliner's patent and its relation to other patents, the term "electrodes" must be divested of its technical sense, and employed simply to designate those parts of the transmitter to which Berliner has applied it in his specifications. It is emphatically important not to allow the term in itself to convey any significance of the essential form, arrangement, or offices of those parts, but to be merely a symbol of reference to the drawings and specifications. Broadly speaking, the parts—those specially designated as electrodes—are certain metallic elements, between the several portions of which a constant contact is maintained. This contact is specifically stated to be constant; that is, continuous, and never to be interrrupted by the normal service of the transmitter, and means are provided for preserving this contact unbroken within the limits of such sonorous vibrations as the instrument is adapted to. Finally, Mr. Barrett comes to the conclusion that—"It may be held that Berliner's claims would surround any transmitter in which the continuity of the conductor is maintained, while the electrical resistance is increased through an elongation and constriction of the conducting path by the separation of short-circuiting areas of contact between mutually respective surfaces of portions of the resistance organism, and decreased by the reverse action. It is consequently not to be confidently asserted that the spiral-spring continuous-conductor short circuiting transmitter is a distinct type not infringing the Berliner claims."

LEGAL INTELLIGENCE.

In re The International Cable Company (Limited).

In the liquidation of this Company several questions arose as to the right of the Directors to remuneration in respect of their services, the most important point being whether they were entitled to claim remuneration during the period between the presentation of the winding-up petition and the making of the winding-up order at the same rate as if the Company were a going concern. The Company was incorporated in 1885 for the purpose of establishing, maintaining, and working certain lines of telegraphic communication. A material part of the Company's undertaking consisted of a concession from the Portuguese Government for landing and working submarine telegraph cables at the Azores from Great Britain, Ireland, and various other countries. Difficulties, however, arose in connection with this concession which resulted in its revocation by the Portuguese Government. A petition was accordingly presented on December 16, 1889, for the winding up of the Company, on the ground that the substratum of the Company was entirely gone. The Directors, however, entertained the hope that the concession might still be obtained, and accordingly they resisted the petition, and at the hearing his Lordship directed it to stand over until July. The hopes of the Directors, however, were not realised, and on the 26th of that month the usual winding-up order was made. The matter now came before the Court upon two summonses. The first was taken out by the liquidator, and by it he sought to make two of the Directors, Sir Alexander Armstrong and Mr. Mowatt, refund certain sums which they had paid to themselves in respect of their fees, on the ground that they had not acquired the necessary qualification shares entitling them to act as Directors. It appeared that the Articles of Association required each of the first Directors to hold 50 shares of £10 each or £500 stock, while all future Directors were to hold 100 shares of £10 each or £1,000 stock. It was admitted by the respondents, who were not first Directors, that they did not hold more than 50 shares each; but they relied upon certain resolutions which were passed by the shareholders on May 16, 1839, altering the Articles of Association in that respect, as a ratification by the Company of their appointment as Directors, notwithstanding they had not taken the necessary qualification shares. The second summons was by Sir A. Armstrong, and it raised the question as to his right to prove for fees in respect of the period between the presentation of the petition and the making of the winding-up order. Sir A. Armstrong claimed fees not only as a Director, but also as Chairman. The remuneration prescribed by the Articles was very large, the sum of £5,500 a year being divided among the Directors and Chairman and Vice-Chairman, and it was stated that similar claims by the other Directors were depending upon the decision in this case. As will be seen, his Lordship reserved his judgment upon the first summons, but disposed of such of the questions arising on the second as were not governed by the first.

Mr. Graham Hastings, Q.C., and Mr. Grosvenor Woods appeared for the liquidator; and Mr. Buckley, Q.C., and Mr. John Chester for the Directors.

At the conclusion of the arguments,

Mr. Justice STIRLING said that in this case there were two summonses. The first was by the liquidator, asking that the Directors might be ordered to refund certain sums which they had paid themselves. The other was by the Directors, seeking to prove in the winding-up for their remuneration subsequent to March 31, 1889, the date up to which they had so paid themselves. As to the first summons, his Lordship had made up his mind; but he did not propose to give judgment on the present occasion, because there was another case in which he intended to give judgment, and in which he would have to deal with the same authorities. As to the second summons he would also say nothing at present regarding that portion of it referring to the period prior to the date of the resolution reducing the qualification of Directors. But from May 16, 1889, when that resolution was passed, to December 16th, when the winding-up petition was presented, he was of opinion that proof ought to be admitted. As to the period from the presentation of the petition to July 26, 1890, when the winding-up order was made, he would order an inquiry in Chambers as to whether any and what remuneration should be paid to the Directors for the period between the presentation of the petition and the making of the order. Regarding Sir A. Armstrong's claim for the higher remuneration as Chairman of the Company, his Lordship held that Sir Alexander had never been formally elected Chairman of the Company within the meaning of the Articles of Association, and was, therefore, entitled to remuneration only as Director.

On the 10th inst., Mr. Justice STIRLING gave judgment on the remaining points. He pointed out that Sir A. Armstrong had told the Board that he

Digitized by Google

would not accept office as Director unless the qualification was reduced to that of the earlier Directors. The Board seemed to have considered that a reasonable thing; but they could not decide the point. The Company only could do so by altering the Articles; and what the Board did was this: They said that at a particular time they would take the opinion of the shareholders; meantime they would not enforce against these gentlemen the obligations in the Articles of Association, as they were desirous that these gentlemen should give the Company the benefit of their services. His Lordship thought that all this was within the powers of the Directors, supposing them to have acted in good faith, and there was no suggestion that they had not so acted. In May, 1889, the Company did alter their Articles, and reduced the Directors' qualification to 50 shares. It had also been contended for the liquidator that Directors' remuneration must mean remuneration of "duly-qualified Directors." His Lordship could not adopt that contention; otherwise, a Director, who acted before attaining his qualification, under circumstances which might justify his so doing, would be deprived of remuneration for such services. That would not be reasonable; and instead of "duly qualified," the better words would be "duly acting as Director." In his opinion Sir A. Armstrong and Mr. Mowatt duly acted, and were entitled to remuneration accordingly. For these reasons the summons must be refused with costs.

National Telephone Company (Limited) v. John Milne and Son.

The action in the Dundee Sheriff Court at the instance of the National Telephone Company, against John Milne and Son, merchants, Dundee, for £8. 10s. of rent or subscription for telephone connection for the current year to November next (*The Electrician*, January 15, p. 282), came up again on Tuesday last. It was intimated that the case had now been settled, Messrs. Milne having paid the £8. 10s. sued for, and Small Debt Court expenses; the Telephone Company, on the other hand, agreeing to terminate their agreement with Messrs. Milne at November next if the latter desire.

Allison v. City and South London Railway (Limited).

In the Chancery Division of the High Court of Justice, London, on Tuesday, the case of Allison *v.* City and South London Railway Company again came before Mr. Justice Kekewich. In this case an injunction was asked for to restrain the defendants from so conducting their works at Stockwell as to be a nuisance to the occupants of the Stockwell Orphanage. At the trial last June, his Lordship adjourned the further hearing of the case in order that the Company might have an opportunity of abating the nuisance. Since then the Company have fixed a wooden roof under the iron roof over the vertical engines, bricked up the recesses in the engine-house wall, stopped the ventilators in the louvre of the roof facing the orphanage buildings, filled up the cavities in the foundations of the engines with solid material, and removed the Westinghouse air pumps from the engine-house walls adjoining the orphanage. The plaintiffs allege that the works executed have not abated the nuisance.

Mr. Renshaw, Q.C., and Mr. Ingle Joyce appeared for the plaintiffs; while Mr. Cozens Hardy, Q.C., and Mr. Graham represented the defendant Company.

After some discussion, and at the suggestion of his Lordship, it was agreed that Mr. Harris, partner in the firm of Sir F. Bramwell and Co., should visit the spot and see what had been done and inform the Court whether the works caused any annoyance by noise or vibration; and if so, whether it could be removed by any alterations or modification in the buildings.

TRADE NOTES AND NOTICES.

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

The tenth annual edition of the above well-known annual is now ready, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements relating to Central Stations, Electric Railways and Tramways, &c., have been made complete; the tables giving useful data relating to dynamos, alternators, motors, transformers, batteries, &c., have been remodelled and amplified, with the object of giving fuller particulars than hitherto relating to the principal makes of dynamos and other electrical machinery and plant. A new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns; no labour or expense has been spared to make this information complete, and we believe that this new feature will be found of great service to electrical firms having business dealings with the companies referred to. The information given respecting the Local Authorities of Great Britain has been perfected, and is thoroughly reliable.

An important feature is the space devoted to the officials of Foreign and Colonial Governments who have the superintendence of contracts and the giving of orders for electrical plant and apparatus; and as this has been kindly supplied by the various Government departments, it can be relied upon, as can also the particulars given respecting the Home Government departments.

As our readers are aware, the DIRECTORY is due at the end of January, and, as a matter of fact, is kept posted up to within two or three days of the date of publication, as is evidenced by the inclusion of several new firms and changes of address which have only taken place at the extreme end of January, 1892.

The profession will find "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

TENDERS INVITED.—Applications are invited by the Llanelly Local Board for taking over the powers vested in the Board by a Provisional Order obtained last Session for the supply of electricity within the District of the Borough of Llanelly. Applications are to be addressed to the Clerk of the Board, Mr. J. Jennings, before March 5th.

——— The Town Council of Bideford also invite tenders for lighting the town and suburbs. Particulars of Mr. C. W. Hole, town clerk.

TENDERS ACCEPTED.—The Aston Local Board has accepted the tender of Messrs. Fowler, Lancaster and Co. (Limited) to substitute the electric light for gas at the public baths, for the sum of £1,594.

MESSRS. ERNEST SCOTT & MOUNTAIN (LIMITED) ask us to state that they are not affected by the strike on the Tyne.

MESSRS. DOLLOND & CO.—This firm have opened a department for the sale of electrical apparatus, which is under the management of Mr. F. Berrett.

THE FRANKFORT EXHIBITION.—The Committee's Official Report on the Exhibition and the Official Report of the Jurors will be published shortly. Each Report will contain about 400 pages, 4to, and will cost about £1 (postage additional). The Official Report of the International Electrical Congress will not be ready until later, and will cost about 15s., including postage. Subscription orders for these Reports (which will be in German) can be sent to the Publisher of *The Electrician*.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

FEBRUARY 1, 1891.

1,876. R. KENNEDY. Glasgow. Improvements in alternating-current electromotors.

1,878. F. DAVIS and R. E. B. CROMPTON. London. Improvements in means or apparatus for protecting underground electrical conductors.

1,880. A. B. WOAKES. London. Improvements in electrical sound-producing apparatus.

1,883. W. LUCAS and T. A. GARRETT. London. Improvements in electrical telephone transmitters.

1,906. J. G. BYWORTH. London. Improvements in shades for electric lamps.

1,908. T. B. GRANT. London. An improved form of automatic accumulator, charging switch, and safety cutout.

1,924. G. S. GRIMSTON. London. An electric switch.

1,927. W. J. S. BARBER-STARKEY. London. An improvement in secondary voltaic batteries.

February 2, 1892.

2,008. E. RATHBONE. Liverpool. Improvements in electric light decorations.

2,012. G. W. HART. London. Improvements in synchronous electrical signalling apparatus.

2,016. J. PRICE, junior. London. An improved block for use in forming conduits for electrical or other cables or wires, and for analogous purposes.

2,017. G. TURNER. London. A new or improved method of and means for making zinc rods for electric bells and batteries.

2,020. C. W. CATT. London. Improvements relating to electrical signalling on railways.

2,026. H. H. LAKE. London. Improvements in electric telephones. (E. A. Grissenger and T. Grissenger, United States.)

Digitized by Google

2,055 W. L. WISE. London. Improvements in or relating to apparatus for closing electric circuits, for use in connection with position finders or the like. (G. Bertolini, Italy.)

February 3, 1892.

2,064. W. D. PARR. Sheffield. Improvements in the construction of electro-pneumatic presselles for electric bells and signals.

2,106. H. HOWARD. London. Improvements in heating and welding by electricity.

2,109. F. T. HOLLINS. Leytonstone. Improvements in arrangements and apparatus for telegraph message signalling and other purposes.

February 4, 1892.

2,162. R. E. B. CROMPTON and E. A. N. POCHIN. London. Improvements in automatic arc lamps used in projectors or search lights.

2,163. R. E. B. CROMPTON. London. Improvements in electric measuring apparatus.

2,198. F. THORNTON and LATIMER CLARK, MUIRHEAD AND CO. (Limited). London. Improvements in culverts for electric mains.

February 5, 1892.

2,225. G. NAHNSEN. Berlin. Improvements in the method of purifying electrolytes containing zinc, relating to or connected with the electro-metallurgic production of zinc.

2,254. W. P. THOMPSON. Liverpool. Improvements in or connected with the holders of incandescent lamps. (M. Fuss, Germany).

2,260. H. H. LAKE. London. Improvements relating to the heating of metals by electricity and to machines therefor. (G. D. Burton, A. H. Eddy, and G. S. Briggs, United States).

2,278. T. C. MOORE. London. Improvements in and relating to electroliers or pendants and standards for electric lamps.

2,283. B. J. B. MILLS. London. Improvements in systems of electrical distribution. (H. W. Leonard, United States).

2,290. E. E. RIES. Baltimore, United States. Method or process of electric riveting.

February 6, 1892.

2,293. D. TURNER. Edinburgh. Improvements in the method of connecting together the cells in medical and surgical batteries.

2,312. B. M. DRAKE, J. M. GORHAM, and J. SAWORD. Westminster. Improvements in shade carriers for electric lamps.

2,329. O. IMRAY. London. Improvements in process and apparatus for bleaching by electrolysis. (T. J. Montgomery, United States.)

2,330. E. A. GIMINGHAM. London. Improvements in electric switches.

2,336. H. DOYER. London. Improvements in dynamo electric machines.

SPECIFICATIONS PUBLISHED.

1891.

1,804. REDFERN. (W. Lahmeyer and Co.) Electric motors. (Price 8d.)

2,732. WHITE. Electric lamps. (Price 6d,)

3,467. MUNNS. (Smith.) Galvanic battery. (Price 8d.)

4,877. LAKE. (Street and another.) Electric batteries. (Price 6d.)

10,307. COERPER. Dynamo-electric machines. (Price 8d.)

19,233. MUNSIE. Electric railways. (Price 11d.)

20,936. DEWEY. Electric heating. (Price 8d.)

21,245. CLERC AND OTHERS. Electric alarm, etc., clocks. (Price 6d.)

21,870. LAKE. (Clark.) Voltaic cells. (Price 6d.)

21,961. LAKE. (Cuttriss.) Relays, telephones, etc. (Price 8d.)

COMPANIES' MEETINGS.

Cuba Submarine Telegraph Company (Limited).

The forty-first ordinary general meeting of this Company was held on Wednesday last at the Company's offices, 58, Old Broad-street, under the presidency of Mr. Thomas Greenwood.

The SECRETARY (Mr. James Scott) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, the accounts which the Board has the honour to submit for your approval to-day resemble very much those that were presented twelve months ago, the difference on either side being very small. Our income has been £350 more than in the corresponding period of last year, while we have saved about £50 in our working expenses. This gives us £370 to the good, comparing one half-year with another. We have taken from the balance £170 more, which enables us to put to the reserve fund £5,000 for the half-year, as against £4,450 in the corresponding period of the previous year. We have been enabled to do this because we have been very fortunate this half-year in having had no interruption to our cables. No amount whatever has been expended in repairs. Of course that £5,000 goes to the reserve fund against repairs, the average of which will be about £3,000 each half-year. The report is remarkably short, and contains all that is to be said; and unless some shareholders may have some inquiries to make, I do not know at this moment what further information I can give you; therefore, I shall move:

"That the report and accounts for the half-year ended 31st December last, now submitted, be received and adopted."

Mr. ALEXANDER F. LOW: I beg to second the resolution.

The Rev. J. W. BROWN: Before putting the report to the meeting, I should like to ask two questions. The first is with regard to the reserve fund. What is the maximum amount to which it is proposed to be raised? The next is with respect to deposits with banks and other investments. I wish to ask whether in your opinion, and in the opinion of your brother Directors, the sum of £8,000 said to be deposited in the English Bank of the River Plate may be taken at that figure?

Mr. COCHRAN: Will you kindly give us some explanation as to the law expenses, and whether they have occurred in connection with the case at Madrid?

Mr. W. GRIFFITH: The reserve fund at the present time is an important consideration. You tell us that the average cost of the repairs of the cable each half-year would be about £3,000. The interest of the reserve amounts to that sum, and to me it certainly seems time that the shareholders should enjoy the benefit of all the profits made upon their capital. I am certainly in favour of insuring our property against any risks; but if the average expenses for repairs do not amount to more than £3,000, and the income from the reserve fund already exceeds that amount, I think you have reached a point when the reserve is as large as it ought to be. There is also another argument in favour of this. We have been fortunate in having our cables constructed by a company that leases to us, so that we can have a cable on lease. That is another reason why we should not have so large a reserve as other companies less favourably situated. How long have we to pay rent for the cable of 1881, which will ultimately become our property? A previous speaker has alluded to the law expenses. Will you kindly give us some information as to the action referred to, and the likelihood of our success? The shares of the Company are at a low price in the market compared with what they were last year. I should be obliged to you if you would tell us the reason why they are lower now than then.

The CHAIRMAN: I shall be very pleased indeed to answer fully all the questions and observations made; and I shall be able, I hope, to do so not only fully but satisfactorily. I shall answer the smaller questions first. The law charges were the whole of the expenses that have occurred in connection with the case at Madrid. With respect to the 1881 cable, it was taken on lease from February 17, 1881, for 12 years, and the payment of £1,875 for the half-year will expire on February 17, 1893—a little more than twelve months from now. As regards the maximum to which it is intended to bring up the reserve fund, the matter has been mooted on several occasions, and I think the late Chairman gave an intimation that it was desirable that it should be added to until we had received the sum of, at least, £100,000. I think it will be then wise for the shareholders, with the Board, to take into consideration—if they are in a position to have £5,000 available—what is to be done with the money. But I strongly recommend that we should continue the course we have adopted until we have raised the reserve to £100,000. As regards the deposits with the Bank referred to, I was elected by the creditors on the committee of inspection of that Bank, and the High Court of Judicature approved of what the creditors had done. In fact, I am the chairman of that committee. I have taken a prominent position, therefore, and an active part in the preparation of a scheme for the resuscitation of the Bank. It is now under the consideration of solicitors, and is practically, though not absolutely, agreed to by all the members of the committee. It involves the payment to every creditor of twenty shillings in the pound by instalments, and interest on the unpaid instalments until the whole amount is paid. If the scheme is carried out, we shall recover the whole of our money and interest on it. Regarding the possibility of getting new cables laid for us upon the same terms as those of the 1881 cable, I can hold out no hope whatever. We tried it when we laid our last new cable, but we were not able to make terms with the contractors similar to those we made in 1881, because at that time the contractors had a cable prepared which they were unable to dispose of, and they were only too glad to get rid of it. That is not the case now, and probably never will be again. As to the necessity of holding a reserve fund, you are aware that for some years past we have been threatened with opposition. That opposition has gone so far as to obtain from the Spanish Government a concession for the making of a line on the other side of the island of Cuba, which would be in direct opposition to us. We are now receiving from the French Company a large traffic, and we reduced our rates 25 per cent. some little time ago to try to secure it, and prevent the French Company from taking steps to extend their lines, because we hoped to satisfy them that it was impossible to lay a cable and carry messages at less cost than we were doing. I am afraid that we have not succeeded in that. The Board, however, are prepared to make a further reduction if, by so doing, they can secure the traffic. We hold that it is much better to make a reduction and keep the whole of the traffic than not to make a reduction, and be driven to make it afterwards by competition, after part of the traffic would be taken from us. The French Company, by getting that line, would do us a very serious injury, but we have very great hopes that our concession will not be interfered with. I think that can be the only explanation I can give of the reason why the shares in the market have been reduced to the price at which they now stand. But while we pay 8 per cent. on our capital and put by a reserve of £10,000 a year it is nonsense to quote our shares at their present prices unless there was an idea that something was going to happen to the Company. There is a possibility, but I don't think a probability, of a combination being brought against us.

The resolution was then carried *nem. con.*

Digitized by Google

The CHAIRMAN next proposed :—

"That the following dividends for the half-year be now declared upon the shares of the Company, viz., at the rate of 10 per cent. per annum, subject to income-tax, on the Preference Shares, and 8 per cent. per annum, free of income-tax, on the Ordinary Shares, payable on and after to-morrow."

Mr. C. W. PARISH : I beg to second that.

The resolution was carried unanimously.

Mr. GRIFFITH : I beg to propose a vote of thanks to the Chairman and Directors.

Mr. CURRY : I beg to second that.

The CHAIRMAN : I thank you on behalf of my colleagues and myself. We are pleased to find that what we have done meets with your approval, and you may rely upon it that everything that can be done in future to promote your interests will be done.

The proceedings then terminated.

Giant's Causeway, Portrush and Bush Valley Railway and Tramway Company (Limited).

The sixteenth annual meeting of this Company was held last week at the offices, Portrush, Dr. A. Traill in the chair, when the Directors' Report was adopted and the retiring Directors, Mr. C. M'D. Stuart and Mr. W. A. Traill, C.E., were re-elected.

The following is from the Directors' Report :—

"Your Directors beg to submit, for the approval of the shareholders, their annual report to December 31st, 1891, which completes the ninth year since the line was opened for traffic. Your Directors are glad to be able to report another large increase in the passenger traffic in the year, the first-class passengers having increased to 9,292 from 8,943 last year, and 7,845 in 1889; and the third-class passengers having increased to 82,406 from 73,859 last year, and 56,822 in 1889—the total for the year being 91,698, with corresponding receipts, amounting to £2,830. 4s. 2d., as against a total of 82,802, with receipts £2,579. 19s. 5d. in 1890, and a total of 64,669, with receipts £2,338. 11s. 7d. in 1889. The goods and mineral traffic amounted to 181 tons, compared with 316 tons in 1890, and the receipts have been respectively £29. 1s. 5d. and £41. 8s. 11d. The receipts for parcels and miscellaneous traffic have diminished during the year from £77. 7s. to £19. 19s., so that the total receipts from the revenue account have been £2,895. 14s. 7d., as against a total of £2,698 15s. 4d. in 1890. There has, however, been considerable increase on the expenditure side of the account, which shows a total of £1,945. 6s. 6d., as against £1,687. 12s. in 1890, and £1,732. 10s. 9d. in 1889. There is consequently a credit balance on the result of the year's working of £950. 8s. 1d., as against £1,011. 3s. 4d. in 1890, and £381. 18s. 7d. in 1889. This result has again fulfilled the anticipations of the Directors, and is traceable not only to the increase in the passenger traffic, but to the alteration made three years ago in the arrangements with regard to the goods traffic, which had previously been a constant source of loss to the revenue. It will be seen, on an examination of the above figures, that the ratio of expenses to receipts, which was 82 per cent. in 1889, and 62 per cent. in 1890, has been 67 per cent. in the past year. The value of electricity as a locomotive power, when generated by water power, as compared with steam, continues to be shown remarkably. The expenses of the electrical working amounted to £314 for 19,863 miles run, or less than 4d. per mile, while steam power cost £635 for 12,280 miles run, or 1s. 0½d. per mile. Your Directors regret the considerable increase in expenditure during the year, but they have found it necessary to re-fence the line for almost its entire length, to prevent accidents to cattle. They have also paid for the conversion of three waggons into cars out of revenue, and have spent a considerable sum in the renewal of the electrical apparatus; and, as the permanent way and steam engines have been kept in complete order, everything will be found in proper condition for the ensuing season. Your Directors regret that they are not yet in a position to offer a dividend to the shareholders, nor can they do so until the net revenue account is brought into a more favourable position; but they think it is evident from the great improvement which has taken place in the finances of the Company during the last two years, that the time is approaching when they will be able to do so."

Liverpool Overhead Railway Company (Limited).

The half-yearly meeting of the shareholders of this Company was held on Wednesday, at Liverpool; Sir W. B. Forwood presiding.

The CHAIRMAN, in moving the adoption of the Directors' report, which will be found below, said that up to date there had been a total expenditure on the construction of the railway of £257,261. Some delay had been caused in consequence of a strike at the works, where some of the girders were being made; but they were now making rapid progress, and they hoped to have the railway complete and open for traffic some time during the autumn. The Directors had lately visited the Electric Construction Corporation Works at Wolverhampton, where the electric plant was being made. They found that the electric plant was well advanced, and that the Corporation were taking very great trouble and care in testing every piece of the machinery, so that when it was delivered they hoped there would be no breakdowns. The generating station would be in the dock line of railway at the Bramley Moore Dock. They had leased a piece of land from the Dock Board and it was in an exceedingly convenient place. They had no necessity to erect any buildings. Their generating machinery, boilers, steam-engines, and dynamos were directly under the coal railway above. They would obtain the coal at a very low cost, because it dropped down from the railway above directly into the boiler pits, and they would also be able to draw water for condensing and other purposes directly from the dock alongside. It was impos-ible to conceive that electricity could be generated at any lower cost than by the method they were adopting. Tenders for the stations had been received, and would be at once considered by the Directors.

The motion having been unanimously adopted, and the retiring Directors and auditor having been re-elected, the meeting was then resolved into a special meeting, when it was resolved to raise the sum of £75,000 by the issue of a Four per Cent. Debenture Stock.

A third meeting of the shareholders was afterwards constituted, at which a resolution was passed approving of a Bill being introduced into Parliament for extension of time in constructing the railway and to make certain extensions.

The following is the Directors' report adopted by the ordinary general meeting :—

"The Directors have pleasure in being able to report that the main structure of the overhead railway had been advanced to St. Nicholas'-place, where the bow-string spans, intended to carry the line across this space, are in the course of erection. The foundations for the southern section are nearly completed, and many of the columns and cross-girders are in place, and as soon as St. Nicholas'-place is crossed, rapid progress will be made with this portion of the work. Arrangements have been made with the Dock Board to lease a site for the electric generating station at the Wellington Dock; the position immediately under the coal railway and adjoining the dock affords very exceptional facilities for the economical production of electrical power. The electrical equipment and rolling stock are well advanced towards completion.

"The balance brought forward from last half-year to the credit of revenue account was £1,447. 7s. 10d., to which must be added interest allowed by the Company's bankers, &c., £126. 17s. 1d., making a total of £1,574. 4s. 11d.; after deducting £198. 4s. 7d. for interest on amount paid in advance of calls, and cost of administration £462. 12s. 5d., there remains a credit balance of £913. 7s. 11d.

"The Directors retiring by rotation at this meeting are Mr. James Barrow, Mr. Edward Lawrence, and Mr. G. H. Robertson, and, being eligible, offer themselves for re-election. The auditor retiring by rotation is Mr. George Nicholson, who is also eligible for re-election."

NEW COMPANIES, STATUTORY RETURNS, &c.

CANNINGTON, SHAW, AND CO. (LIMITED).—Registered with a nominal capital of £250,000, divided into 2,500 shares of £100 each. Object : To acquire (as from January 1, 1892) as a going concern the business of glass manufacturers, now carried on under the style of Cannington, Shaw, and Co., at the Sherdley Glass Works and the Peasley Glass Works, both situate at Sutton, near St. Helen's, Lancashire.

ROTARY ENGINE SYNDICATE (LIMITED).—This Company was registered on February 8, 1892, as a Company limited by guarantee. For the purposes of registration the number of members is declared to be 100, and should the Company be wound up each member is liable for £20. The objects are to apply for, purchase, or otherwise acquire, any patents, licenses, concessions, &c., and in particular to acquire the inventions for (*a* "an improved rotary expansive steam engine or pump," and (*b*) "improvements in rotary fluid-pressure engines, applicable also as pumps," and to carry on the business of general, mechanical, manufacturing, civil, marine, and electrical engineers, metal founders, machinists, metallurgists, &c. Registered office : Castle Chambers, Apie-street, Norwich.

SHARON CHEMICAL COMPANY (LIMITED).—This Company was registered on February 3, 1892, with a capital of £7,800, divided into 750 ordinary and 30 founders' shares of £10 each, by Waterlow and Sons (Limited), 83, London-wall, London, E.C. The objects are to purchase and take over, as a going concern, the business of chemical manufacturers, carried on at Little Chester, Derby, under the style of "The Sharon Chemical Company," and to carry on the business of analytical and manufacturing chemists in all its branches; to generate for the purposes thereof electricity, gas, or other power, and to use the same. The number of Directors is not to be less than two nor more than five. Qualification, £750. Remuneration of above Directors, £250 each per annum.

TAVERNIER'S FRENCH PATENTS (LIMITED).—This Company was registered on February 3, 1892, with a capital of £1,200 in £1 shares, by Williams and Neville, 23, Austinfriars, London, E.C. The objects are to acquire from [Alphonse][Edouard] Tavernier an invention described as an electrical apparatus for the automatic indication of fire, and of the rise of temperature in the bearings of machinery, and for simultaneously supplying oil where required; to acquire any other invention, addition, or improvement, and to utilise and turn to advantage the said inventions, brevets d'invention, rights and privileges by manufacture and sale, grants of licenses to manufacture and sell, by further development, &c. The Regulations of Table A. mainly apply.

TROTT PATENT VALVE AND ENGINEERING COMPANY (LIMITED).—This Company was registered on February 3, 1892, with a capital of £50,000, divided into 49,500 ordinary and 500 founders' shares of £1 each, by Lickorish and Bellord, 11, Queen Victoria-street, London, E.C. The objects are to enter into an agreement with Herbert Trott, for the purchase of certain letters patent, trade marks, rights and premises, to carry on the

Digitized by Google

business of manufacturers and vendors of Trott's patent valves and apparatus, and generally to carry on the business of iron, brass, and metal founders, fitters, mechanical engineers, manufacturers of agricultural machinery and implements, tool makers, metal workers, boiler makers, iron and steel converters, electrical, hydraulic, sanitary, marine, gas, and water supply engineers and suppliers of electricity for all purposes.

MISCELLANEOUS.—Amongst the new Companies recently registered which propose dealing in some way or other with electricity, are—

Kennedy Dry Press Brick Machine Syndicate (Limited); capital, £15,000.
Pontnewynydd Freehold Land Building and Cottage Company (Limited); capital, £25,000.
W. Summerscales and Sons (Limited); capital, £50,000.

AUTOMATIC ELECTRICAL CORPORATION (LIMITED).—The annual return of the above-named Company, made up to January 14, 1392, was filed on the same day. The Company was registered on June 7, 1888, with a capital of £75,070 in £20 shares, to act as undertakers for the supply of electricity for lighting and other purposes within the United Kingdom and elsewhere, and to erect and manufacture apparatus for the generation and supply of electricity. At the time of making-up all the shares had been taken up, and upon 7 of these the full amount had been called and paid. The remaining 3,743 shares have been issued and considered as fully-paid. Registered office: Winchester House, Old Broad-street, London, E.C.

BARNET AND DISTRICT ELECTRIC SUPPLY COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 12, 1892, was filed on the same day. The Company was registered on August 25, 1888, with a capital of £5.0 0, divided into 490 ordinary shares of £10 each, and 100 founders' shares of £1 each, to acquire all the rights, benefits, and advantages of H. F. Joel, under a contract with the Barnet Local Board, for the lighting of the district of the Board by electricity, and the supply of electricity to shops, private houses, and other buildings, and to carry on the business of an electric light, heat and power supply Company in all or any of its branches. At the time of making up 80 ordinary and 100 founders' shares had been taken up, the founders' shares having been issued as fully paid. Upon 60 ordinary shares the full amount has been called, and upon the remaining 20 £5 per share has been called, and all calls have been paid. Registered office: 31, Wilson-street, Finsbury, London, E.C.

BRITISH ELECTRIC LIGHTING COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 13, 1892, was filed on January 21st following. The Company was registered on October 4, 1878, with a nominal capital of £100,000, in £10 shares, for the "bringing into public notice the advantages of electric force and power as an agent in producing light for general illuminating purposes, and extending its adoption and use for such purposes, and the acquisition of gain and profit by employing, using, and utilising electric force and power as an agent in producing light, and the utilising of light so produced for general lighting and illuminating purposes." The Company filed returns regularly until January 19, 1886; and on Saturday, February 13, 1886, in the High Court of Justice, Chancery Division, upon the petition of S. S. Stott and Co., engineers, of Laneside Foundry, Haslingden, Lancashire, Mr. Justice Pearson ordered that the Company be wound up under the provisions of the Companies' Acts, 1862 and 1867. On Wednesday, Sept. 26, 1888, however, in the High Court of Justice, Chancery Division, upon the petition of H. T. Edwards, the official liquidator of the Company, Sir James Hannen (for Mr. Justice North) ordered that all further proceedings in the winding-up of the Company should be stayed, and the Court sanctioned a scheme of arrangement with the debenture holders, unsecured creditors, and shareholders, by which "the unsecured creditors should respectively accept fully paid-up preference shares, carrying interest at 10 per cent. per annum, for amounts equal to 50 per cent., or one-half of their respective debts or claims against the Company, in full satisfaction and discharge of such debts and claims respectively." At the time of making up (January 13, 1892), 8,640 shares had been taken up, of which 1,144 had been issued as fully-paid; upon the remaining 7,496 the full amount has been called and paid. Registered office: 11, Delahay-street, Westminster, London, S.W.

CLEGG'S METAL INCANDESCENT LAMP COMPANY OF FRANCE (LTD.).—The registered offices of the above-named Company, which was registered on May 20, 1891, with a capital of £10,000 in £10-shares, have been removed from Wharf-road, City-road, London, and are now situate at Connaught-mansions, Victoria-street, Westminster, London, S.W.

COLUMN PRINTING TELEGRAPH COMPANY (LIMITED).—Although this Company was registered on June 5, 1890, no information respecting its shareholders has been filed. The capital of the Company is £100,000, in £1 shares, and the Directors were the Right Hon. the Earl of Wharncliffe, Viscount Lymington, Hon. Arthur Brand, W. H. Hurlburt, and R. Pryor. Registered office: 5, New Bridge-street, London, E.C.

ELECTRIC METER COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 13, 1892, was filed on January 21st following. The Company was registered on March 22, 1890, with a nominal capital of £50,000, in £10 shares, to enter into an agreement with the Corporate Trust (Limited) for the sale to the Company of certain letters patent relating to electric meters and other rights, and to carry on the business of electricians, mechanical engineers, manufacturers of any kinds of electrical apparatus and appliances, workers and dealers in electricity, motive power, and light, telegraph, cable, and telephone manufacturers, &c. At the time of making up, 2,007 shares had been taken up, of which 2,000 were issued as fully paid. Upon the remainder the full amount has been called, resulting in the payment of £30, and leaving £40 in arrears. Registered office: 25, College-hill, Cannon-street, London, E.C.

LAW'S ELECTRICAL APPLIANCES COMPANY (LIMITED).—The statutory return of the above-named Company, made up to February 3rd, 1892, was filed on February 5th following. The Company was registered on September 23rd last, with a capital of £4,000 in £5 shares, to acquire and work certain patents for "Improved methods for facilitating the publication of news," "Improvements in apparatus for operating or controlling type-writers, type-setting machines, and the like by the aid of electricity," "Improvements in and relating to electrical switches, chiefly designed for use in connection with apparatus for obtaining synchronous movements," belonging wholly or in part to Edward Fitzgerald Law. At the time of making up, 793 out of the 800 shares had been taken up, of which 786 had been issued as fully paid. Upon the remaining 7 no calls have been made. Registered office: 2, Jackson-road, Holloway, London, N.

RICHARD HORNSBY & SONS (LIMITED).—The annual return of the above-named Company, made up to December 23, 1891, was filed on December 30, 1891. The nominal capital is £400,000, divided into 30,000 ordinary shares of £10 each and £100,000 worth of Preference stock. The 30,000 ordinary shares and all the Preference stock has been taken up, and upon the ordinary shares £8 per share has been called and paid, while the whole of the Preference stock has had the full amount called and all calls paid, the amount paid being £340,000.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to allow this Company's 5,004 additional preference shares, Nos. 69,997 to 75,000, to be quoted in the Official List.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—Mr. James Staats Forbes, the Chairman of the London, Chatham and Dover Railway Company, in addressing the shareholders at the ordinary meeting at the Cannon-street Hotel on Friday, said that the Company had to contend with most serious competition of omnibuses, tramways, and electric railways. The latter were no doubt matters of great public convenience. The only one which was now working in London was, he believed, the City and South London Railway, which ran for some distance parallel to the line of their railway. That Company had just published their report, and he hoped that the people who had put money into that enterprise would find comfort in the report that had been issued. They had carried a very great many passengers who would no doubt, had that railway not existed, have gone over their Company's system; but he did not think that they had done very much good for themselves: but still, it was a great convenience to the public. The Chatham line must to some extent have suffered in consequence, and they were not the only sufferers because it had also affected the tramway companies on the other side of the water, who had had to reduce their fares, and who, he believed, for some considerable distance south of the river were now carrying their passengers for ½d., in consequence of the competition of the electric line. The London, Chatham and Dover Company could not afford to carry people on their railway for ½d., neither could they afford to carry them for 1d., because the people who wanted to travel in large numbers at ½d. and 1d. required to travel at the very hours of the day, coming into London and going out of London, that the high-class people—the long-distance traffic people—required to get in and out; and therefore it was a question of selection, and they could not sacrifice the long-distance and paying traffic for the advantage of the masses. He had no hesitation in stating as a proposition that no company could make a railway, whether it was under ground or whether it was over ground, in London for local accommodation at these low fares that could possibly pay.

The declaration of the result of the poll demanded at the shareholders' meeting held last week (see *The Electrician*, Feb. 6, p. 368) took place on Tuesday last, at the office of the Company, 46, King William-street, E.C., when the Chairman (Mr. Chas. Grey Mott) announced that the resolution had been carried by a large majority.

The traffic receipts for the week ended February 7th amounted to £824, as against £702 for the corresponding period of 1891, an increase of £122. The total receipts to date, from January 1, 1892, are £4,475, against £4,033 in the corresponding period of 1891, an increase of £442.

CITY AND WATERLOO RAILWAY COMPANY (LIMITED).—Mr. W. S. Portal, the Deputy-Chairman of the London and South-Western Railway Company, in the course of his speech at the annual meeting held on Thursday last, referred to the Waterloo and City Railway Bill, and said that the most important of the Bills the progress of which they were watching through Parliament was the Waterloo and City Railway Bill, which it was manifestly in the interest of their Company to support. This Bill was promoted in the present Session of Parliament for powers to make an underground railway from Waterloo Station to the City, the terminus of the same to be very close to the Mansion House. The promoters of that Bill took powers under the Bill to enable them to enter into arrangements with the London and South-Western Railway Company. They had no doubt whatever that if such a Bill were approved and the railway made, it would be of immense advantage for the improvement of the residential traffic of the London and South-Western Railway, and altogether they considered that it would be of great benefit to that Company. For many years past they had been twitted with the fact that they landed their City passengers at Waterloo Station, and did not carry them on to the City. They had had many schemes submitted to them for carrying out this purpose, and they had always brought to bear a large amount of attention upon this important subject; but they had arrived at the conclusion that it would not be wise

Digitized by Google

to incur an expenditure of some £3,000,000 or £4,000,000 of money which they would have to do in order to make this line. But *tempora mutantur!* Science was not stationary, and with the progress of electrical science had come the possibility of constructing this line for something like only half a million of money. At the special meeting which followed the general meeting it was unanimously resolved to support the Bill.

ELECTRIC CONSTRUCTION CORPORATION (LIMITED).—The Stock Exchange Committee have ordered the vendors' shares, Nos. 45,101 to 50,000, to be quoted in the Official List.

GREAT NORTHERN TELEGRAPH COMPANY (LIMITED).—The traffic returns of this Company in January, 1892, were £20,000; corresponding month, 1891, £20,800; 1890, £19,600.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to allow this Company's 10,000 additional Seven per Cent. Preference shares, Nos. 30,081 to 40,080, to be quoted in the Official List.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED).—Subject to the audit of the accounts, the Directors propose paying a dividend of 15 per cent. (£1. 16s. per share), in addition to the 5 per cent. already paid, making 20 per cent. for the year 1891.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—Application has been made to the Stock Exchange Committee to appoint a special settling day in, and to grant a quotation to, this Company's £80,000 Five per Cent. First Mortgage Debentures (1917).

THE ELECTRICIAN:

A WEEKLY LLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 718.—Vol. XXVIII. FRIDAY, FEBRUARY 19, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/6

NOTES.

The regulations which have been made by the County Council "with respect to the requirements for the protection from fire of theatres, houses, rooms, and other places of public resort," and which will be found elsewhere in our present issue, are very ambitious in their scope; but on the whole they ask for little that is unnecessary, and it is well to err on the safe side in such matters. Many structural regulations as to the details of the building have been in force for some years, and to these have been added from time to time many minor matters about locks and staircases. The rules for electric lighting are rather more detailed, but do not differ more from those which have been drawn up for ordinary work than is called for by the peculiar circumstances. As part of a specification for the fitting of a new theatre these regulations are excellent, but it is difficult to guess how far they are intended to be applied to existing houses. "Principal resistances shall be placed in a fire-proof room reserved for the purpose" is a good suggestion for the architect when engaged on designing a new building; but when every square foot of space under or near the stage is fully occupied, as is the case in nearly all theatres, nothing that can be called a "room" can be constructed without serious difficulty and expense.

It is directed that gas-engines shall be placed in rooms so adequately and continuously ventilated that no explosive mixture of gas can accumulate by any leakage through the engine, in the event of any of the gas-cocks being left turned on. This is practically forbidding the running of gas-engines in basement-rooms, and nothing short of an open shed would meet the conditions. A plan of the wiring is ordered to be kept always in a prominent position in the office of the manager of such premises. What is then to become of all the photographs, testimonials, and playbills? A plan of the wiring of an ordinary large house is complex enough, but the representation of the circuits which are constantly being altered in a well-equipped theatre would be enough to puzzle even a County Council inspector.

Like many of those who were present at Mr. Tesla's lectures, a correspondent who writes to us this week has been led to imagine that certain of his striking experiments are altogether new, while they really consist in repetitions of well-known effects on a large scale; and no one is better aware of this than Mr. Tesla himself. The glowing wires which excited so much interest were a reproduction, in a more brilliant style, of the experiment which was shown by Dr. Oliver Lodge at the Physical Society on June 12th last, and which was described on p. 200 of our last volume. Dr. Lodge's wire did not glow so brightly, it is true. He had a single wire about 60ft. long, and nothing more than a couple of Leyden jars and a Wimshurst machine were used. The length of the wire had been arranged to be in resonance, or syntony, with the jar, and thus distinct stationary waves were set up, part of the wire being dark and part bright. We are not aware whether Mr. Tesla has attempted to reproduce this interesting effect. The experiment with the concentric rings appeared to be more of the nature of a brush discharge. Our correspondent assumes that some appreciable current was passing, and that the space surrounding the conductor was "imbued with magnetism." It is doubtful whether in the majority of the experiments a single milliampere was used; and though Mr. Tesla has not yet proved that Prof. J. J. Thomson's experiments are not electro-magnetic, he seems justified, in the sense in which he uses the expression, in contending that all his own results are purely electrostatic.

It is as impossible to separate electro-magnetic phenomena from electrostatic, as to draw a line between kinetic and potential forms of energy. When the currents and potentials under investigation are steady, it is comparatively easy to distinguish between the electric and magnetic parts of the phenomena; but in electrical oscillations, such as Hertz, Tesla, and Thomson have worked with, the currents and potentials are constantly changing, and theory indicates that each electro-magnetic disturbance must then be accompanied by a corresponding electrostatic one at right angles to it, and *vice versa*. Since both kinds of disturbance must exist together with rapid oscillations, it is necessary, before any phenomenon can be called electrostatic, to know what is meant by the electrostatic effects being more important than the electro-magnetic ones. As far as we are aware, no one has yet clearly pointed this out.

The aurora borealis must, according to the common use of the terms, be electrostatic or electro-magnetic. It is more easy to theorize in a random fashion on the electrostatic hypothesis, and to talk about electrical discharges between cold and warm, or dry and moist, streams of air in the upper regions. It would not be difficult to account for

Digitized by Google

the necessary volts; but the amperes, too, would have to be enormous to produce the magnetic disturbances which accompany these displays.

CONNECTED, no doubt, in some way which science has not yet discovered, with the huge spot which sailed across the disc of the sun this week, disappearing yesterday on the receding limb, and followed by a trail of four others, which may now be seen through a comfortable thickness of fog without a telescope, a magnificent aurora has been witnessed this week both in America and in Norway, and the telegraphic systems have been seriously affected. Powerful but unsteady currents of greater strength than the ordinary working currents interrupted the lines between New York and Albany for nearly two hours. An attempt to work a Wheatstone instrument on a line between Lyons and Paris on Saturday had to be given up. A sudden outburst occurred at about four o'clock on that afternoon, lasting about two hours, and an earth-current of 10 milli-amperes was recorded at Inverness, where the telegraphic business could only be carried on at intervals; and a renewal of the disturbance was observed at midnight.

THE blizzard, the fashionable name for a sharp snowstorm, has been attributed to the sun spots and the aurora. The Russian famine has already been accounted for and is a little out of phase, or this might be dragged in. The Bank rate, another matter which is supposed to be connected with solar activity, has as yet been unaffected.

IN a Note appearing in *Atti della Regia Accademia delle Scienze di Torino* Prof. GALILEO FERRARIS claims to have been the first to use the three-dynamometer method for the measurement of energy dissipated in hysteresis and eddy currents in transformers. In a Note presented to the same Academy on December 4, 1887, "*Sur la différence de phase des courants, sur le retard de l'induction, et sur la dissipation de l'energie dans les transformateurs*," the Professor showed methods of measuring not only the difference of phase between the primary and secondary currents, but also many important energy losses occurring in transformers. The three-dynamometer method for measuring difference of phase was first described by Mr. BLAKESLEY in *The Electrician* for October 2, 1885, and Prof. FERRARIS acknowledges priority in so far as this is concerned. He, however, says, "But Mr. BLAKESLEY's claim of priority only extends to the measurement of phase, and does not apply to the principal part of my work, the discussion of the results, and the numerous conclusions which I drew from them. Now two months after making this claim of priority (Physical Society, March 10th, 1888), and having thus knowledge of the existence of my work, Mr. T. H. BLAKESLEY at the meeting of the Physical Society, of May 12th, 1888, read a Note entitled 'Magnetic Lag,' in which he makes no allusion to my work, and re-establishes the same formula to which I had arrived. I should not have made any personal claim if my conclusions had not received important applications in the work of Professor AYRTON and Mr. J. F. TAYLOR (*Phil. Mag.*, 1891), and others, who in their memoirs have attributed to BLAKESLEY the formulæ which I established, and which are still true when the current is no longer sinusoidal, and is consequently intractable for purposes of calculation."

WHEN electric mining machinery was being discussed last year at the Institution of Civil Engineers, the only percussive drill that was described was an Ingersoll, driven by an ordinary electric motor. More than one speaker alluded to the electric reciprocating drills in use in America, and it was understood that these were fairly successful. The Marvin drill was described in our columns more than two years ago; and the Van Depoele drill, which was shown at the Frankfort Exhibition, was described and illustrated in the first number of the present volume. The electrical arrangements were very ingenious, and the theoretical difficulties of getting any reasonable efficiency from work done by a solenoidal magnet appeared to have been counterbalanced by the carefully considered mechanical details. But if the information given by the *Engineering and Mining Journal* of New York, which we reproduce in another column, is correct, these electric reciprocating drills have by no means fulfilled the promises which were made for them. It is true that the most serious defect which presents itself, viz., the heating of the solenoids and the piston, ought to be avoided to a great extent, if the arrangement is otherwise efficient, by proper lamination and insulation, while the mechanical difficulties are probably not more serious than those which have always to be met in striking out a new departure. It seems probable, however, that the coil and plunger principle is so inefficient as a motor that a very large current must be used to do the work, and that this is the cause of the trouble.

Telegraphic Communication with Fort Salisbury.—Telegraphic communication was on Wednesday finally established between Fort Salisbury and the Cape.

Proposed Teaching University for London.—The Privy Council have agreed to the proposed Teaching University for London being designated "The Gresham University."

Royal Society.—Among the Papers down for reading before the Royal Society yesterday was one by Lord Rayleigh, "On the Relative Densities of Hydrogen and Oxygen. No. II."

Bockenheim.—The town of Bockenheim has granted a concession for the supply of light and power by means of electricity for forty years to Lahmeyer and Co., of Frankfort-on-Main.

Glasgow.—Two members of the Gas and Electric Lighting Committee of the Corporation and three officials have been deputed to visit London to study street lighting by electricity.

Alternate-Current Motors.—The printing presses of the *Fremdenblatt*, says *Industries*, are now driven by means of alternate-current motors, current for which is obtained from the central station of the Internationale Electricitäts Gesellschaft.

"L'Elettricista."—We have received No. 1 of a new monthly electrical journal with this title, which is published in Rome under the direction of Signori F. Cardarelli, I. Brunelli, and A. Banti.

A Statue to Fresnel.—The Société Française de Physique are about to get up a subscription for the purpose of erecting a statue to Fresnel, and keeping his tomb at Père-Lachaise in repair.

Mr. Nikola Tesla.—Mr. Nikola Tesla will deliver a lecture this evening to the Société Française de Physique and the Société Internationale des Electriciens, in the hall of the Société d'Encouragement, at 44, Rue de Rennes, Paris.

The Waterloo-City Electric Railway.—The Lambeth Vestry have decided to oppose the Waterloo and City Railway

Digitized by Google

Bill if the promoters do not insert a clause providing cheap fares for the working classes.

Liverpool.—At the last meeting of the Watch Committee it was finally decided to agree to the Liverpool Electric Supply Company's proposed Provisional Order upon the terms stated in our Notes column last week.

Hove.—An inquiry has just been held by the Local Government Board into the application of the Hove Commissioners for permission to borrow £1,400 for the purchase of land for the erection of an electric central station.

Hanley.—At a meeting of the Hanley Town Council, on Wednesday last, it was resolved to advertise for specifications and estimates of the cost of plant and distributing mains and machinery for lighting by electricity the area contained in the Hanley Provisional Order.

Leeds.—The managers of several of the leading banks, as well as the secretaries of some of the most important clubs and others, have issued a joint appeal to the Corporation asking that steps should be taken to secure for the town a supply of electricity at a reasonable rate.

Accumulator Cars in Rome.—An accumulator car is about to be tried in Rome. The motors and the accumulators are supplied by the Oerlikon Company, and it is proposed to commence a regular service of accumulator cars if satisfactory results are obtained with this first one.

The Telephone and the Post Office.—Dr. Cameron has given notice to call attention, on the Civil Service Estimates, to the relations between the Postal Telegraph Department and the telephone system. He will bring forward a motion in favour of the acquirement of the telephone system by the Post Office.

Useful Applications of Electricity.—Last week at the St. Paul, Shadwell, Mutual Improvement Association, Mr. W. H. Winny, A.I.E.E., delivered a lecture on the above subject. The lecture was illustrated by a number of experiments, and a hearty vote of thanks was passed to Mr. Winny for his demonstration.

St. Petersburg Electrical Exhibition.—A German paper states that in consequence of some defect in the conduits containing the electric light cables, it was not possible to switch on the current on January 23rd and 24th; and the Exhibition was, therefore, not opened on those days, involving a loss of some 3,000 roubles.

The Telephone Service of London.—We call attention to the fact that a special general meeting of members of the London Chamber of Commerce will be held at Botolph House, Eastcheap, on Monday next, at 2:30 p.m., for the purpose of discussing the general position of the commercial community in regard to the telephone service of London, and the Telephone Bills now before Parliament.

Electric Drilling.—We mentioned last week that Messrs. Bell Bros., of Middlesborough, were about to adopt electricity as a means of transmitting power to drills in their Cleveland ironstone mines. This work is being carried out by Messrs. D. Selby Bigge and Co., of Newcastle-on-Tyne, who have done much to advance electric mining in that district, several power plants having been recently installed by them.

The Cork Gas Company and the Electric Light.—At the meeting of the shareholders of the Cork Gas Consumers' Company yesterday it was announced that the Corporation, without giving any reasons, had refused their assent to the Company's Electric Lighting Order. Although such assent is not legally necessary, the Directors have deemed it wiser for the present not to take any further steps to obtain an order in the present Session of Parliament.

The Brighton and Hove Electric Lighting Company.—This company has issued a circular setting forth the history of the undertaking and detailing the treatment it has met with at the hands of the Town Council, the Board of Trade, and the Local Government Board. A clearer case for just if not generous dealing was never made out; and it is most difficult, especially when we remember that the whole local press has supported this view, to understand why the Town Council should have acted otherwise than fairly.

Coast Lights.—In answer to some questions addressed to him in the House of Commons last week, Sir Michael Hicks-Beach stated that he had been in communication with the Trinity House, who stated that whether the Wigham light at Tory Island was more effective in fog could only be estimated from the results of experiments at South Foreland, which were conclusively in favour of the electric light. Experiments in sky flashing, so far as they had gone, had not been encouraging for the adoption of that system. The Elder Brethren were in communication with the Shipmasters' Society on the subject.

The Weight of Incandescent Lamps.—In view of the tax now imposed on all incandescent lamps imported into France, the following figures from *L'Industrie Electrique* are of interest:—

One hundred 100-volt c.p. Lamps.

	Weight. (kilogrammes).	Duty (francs.) Ordinary.	Minimum.
Fitted with eyelets	1·7	13·6	11·9
Fitted with copper bases	2·8	11·2	9·8
Fitted with vitrite sockets	3·4	13·6	11·9

A complete list of electrical articles affected by the new tariff appeared in our issue of January 22nd.

Southport.—At the last meeting of the Town Council the Foreshore and Improvement Committee was authorised to purchase an electric launch for use on the new marine lake. The electric lighting sub-committee recommended the rescinding of a resolution providing, amongst other things, that the Southport Electric Lighting Order, 1891, be put into force by the Corporation, without delegating the powers thereby conferred to a private Company. It was resolved that this portion of the resolution be rescinded, and that a circular be issued to all householders in the scheduled area asking them if they intend to light their premises with the electric light.

The Magnetic Properties of Oxygen.—Commenting on Prof. Dewar's recent experimental verification of the magnetic properties possessed by liquid oxygen, M. Guillaume points out in *L'Industrie Electrique* that if we accept the values found by Edmond Becquerel for the magnetic constant of oxygen, it ought, when in the liquid state, and in a field of medium strength, to possess a magnetic moment per cubic centimetre, one-third of that of iron, and a magnetic moment per gramme twice as great as that of iron; so that the strange conclusion is forced upon us that oxygen is the most magnetic of substances. M. Guillaume also points out that liquid oxygen might be made to give a faithful and delicate representation of the distribution of the lines of force in a magnetic field, the liquid being heaped up in the strong places.

The Electric Railway Schemes.—Mr. Whitmore has given notice of his intention to move:—"That a Joint Committee of Lords and Commons be appointed to consider the best method of dealing with the electric and cable railway schemes proposed to be sanctioned within the limits of the metropolis by Bills introduced, or to be introduced, in the present Session, and to report their opinion as to whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and probable future traffic; as to whether any, and which, of the schemes propose satisfactory lines of route; as to the terms and conditions under which the subsoil should be appropriated; whether any, and, if any, what, schemes should be proceeded with during the present Session. That a message be sent to the Lords to communicate this resolution, and desire their concurrence."

Continuous-Current Transmission of Power.—Le Compagnie de l'Industrie Electrique Genève have just erected an interesting electric transmission of power plant in the neighbourhood of Genoa. Constant-current motors are employed, the largest of which absorbs 1,000 volts, or 50 kilowatts, the current being about 50 amperes. The source of power is 30 kilometres distant from Genoa, but the first motor is only 8 kilometres from the turbine station. When all the dynamos are at work the pressure amounts to 3,000 volts; it will soon be 6,000 volts; and a maximum of 8,000 volts is contemplated. Carbon brushes are employed, and give every satisfaction. Three stations will ultimately be at work, but only one is now in operation. The first station is 2,000ft. above the town of

Digitized by Google

Genoa, water-power being obtained from the artificial lake which acts as a reservoir to the town supply; there is a water storage of 4,000,000 cubic metres (880×10^6 gallons). The second station is 400ft. below No. 1. Here there are four 140-H.P. Faesch-Piccard turbines, each driving a pair of 70-H.P. 1,000-volt dynamos, coupled in series. The third station is some 460ft. below No. 2, and the plant comprises one 140-H.P. turbine and two 300-H.P. turbines. The 140-H.P. turbine drives two 70-H.P. 1,000-volt dynamos. There are three circuits of 9mm. wire, each supplied by a separate station.

Bradford.—We were unable last week to accept as accurate the *Bradford Observer's* report of Mr. Alderman Priestman's remarks with reference to the cost of coal at the municipal central station. In the original report it was stated that "the cost of coal per Board of Trade unit had been 12·58d." To find what this figure actually meant we took Mr. Alderman Priestman's figures for coal consumed (865 tons) for price per ton (7s. 7d.) and for units sold (154,431) as correct, and worked out the cost of coal per Board of Trade unit at ·58d., and the coal consumed per Board of Trade unit at 14½lb. The passage, we are authoritatively informed, should read as follows:—"The coal which had been consumed during the half-year, without reckoning the stocks at the beginning and end, which were about the same, was 867¼ tons, or 1,942,640lb. The total cost of the coal had been £342, and when he reckoned the number of Board of Trade units sold, which were 154,431, he found that *the consumption of coal per Board of Trade unit had been 12·58lb.*, not 30 and 34lbs., as he had heard it stated outside that building. He believed it was usually admitted that a Board of Trade unit required between 1½ to 2 indicated horse-power to generate; and so, if the matter was reckoned out, it would very soon be found what had been the number of pounds per horse-power that had been consumed. The average price of coal—and this was a very important thing to take into account—had only been 7s. 10½d. delivered at the works."

Obituary.—The death is announced on January 2nd of Prof. Shida Rinzaburo, of the College of Engineering in the Imperial University of Japan, and formerly Director of the Engineering Bureau in the Department of Communications. Twelve years ago Prof. Shida, with a band of fellow graduates of the Imperial College of Engineering, sailed for Europe to prosecute studies in physical science. Three of the band attended Sir William Thomson's classes at Glasgow University. Prof. Shida scored a brilliant success by securing the first place in the Natural Philosophy and Higher Mathematics classes, and impressed Sir William with a high opinion of his powers. His Paper on the "Magnetic Susceptibility of Iron" secured a gold medal from the Royal Society. During the seven or eight years of active life that were vouchsafed to Prof. Shida, he did notable work in the University, in the capital, and in the provinces; and perhaps to him more than any other is due the credit of bringing the telegraphic system of Japan to its present state of efficiency. An energetic member of the leading scientific societies of Tokyo, President of Council of the Electrical Society, a brilliant lecturer, and original investigator, his loss will be severely felt. Born 35 years ago in the province of Saga, Prof. Shida entered the Imperial College of Engineering in the year 1874, and had a successful course as a student. For some time back he had been suffering from consumption, which developed very rapidly at the close, so that his death came as an unexpected shock to his many friends.——The death is also announced of Dr. T A. Hirst, F.R.S. Dr. Hirst was born in 1830, and early in life made the acquaintance of Prof. Tyndall. In 1861 he was elected a Fellow of the Royal Society. He was also one of the original members of the London Mathematical Society, which was founded in 1864, under the presidentship of Prof. De Morgan. In 1865 Dr. Hirst was appointed Professor of Mathematical Physics in University College, London, which chair he held until 1867, when he succeeded De Morgan as Professor of Mathematics in that College. In 1870 he accepted the newly-created appointment of Assistant-Registrar in the University of London. Early in 1873, when the Royal Naval College was founded at Greenwich, he became director of studies, and held the post for ten years. Dr. Hirst was three times a member of the Council of the Royal Society, and twice one of its vice-presidents. In 1883 one of the Royal medals was awarded to him. He was also a Fellow of the Royal Astronomical Society, a member of the Physical Society, an *ex officio* member of the Council of the British Association. He served for some years on the Council of University College, London, and in 1882 was made a Fellow of the University of London.——Major-General Ryrie Alexander, who for the past three years has acted as chairman for Messrs. Shippey Brothers (Limited), and who was connected with several other electrical companies, died on the 10th inst., at his residence, Redwall, Dartmouth, Devon.——The death is announced of Prof. William Dittmar, F.R.S., Professor of Chemistry at the Glasgow and West of Scotland Technical College.

The Chicago Exhibition.—We have received the following communication from the Electrical Committee of the Royal Commission for the Chicago Exhibition, 1893:—

The Electrical Committee are anxious that the Electrical Department of the Exhibition should contain a good representation from this country. The British exhibit will include a historical collection as well as the contributions which will be sent in by commercial firms. In addition, it is hoped that a portion of the electric lighting of the Exhibition may be carried out by some British firms, and the Committee think that the arrangements of a complete lighting station on the English method could advantageously be shown at Chicago. From the English point of view it is specially desirable to show how large a share English electricians have had in developing electrical science and its practical applications. The first electrician was an Englishman, Gilbert. It was in England that a practical telegraph line was first worked out by Ronalds in 1816. There are no names more closely associated with the early development of the science of electricity than those of Davy and Faraday. The introduction of telegraphy must inseparably be connected with Cooke and Wheatstone; while the early history of the dynamo would be incomplete indeed without reference to Wylde and Holmes. In England, electricity was first applied to the working of railways, and here nearly all the submarine cables of the world are made. It is hoped that arrangements may be made for showing the fine collection of historical apparatus in the possession of the Post Office, and this will be supplemented by contributions which will be sought from many other sources.

On the commercial side, while there is no disputing that practical electric lighting has made greater progress in America than in this country, there is yet much that England can show electricians on the other side of the Atlantic. The domestic uses of electricity and its artistic application are matters in which they confess themselves to be less advanced than we are, and probably many firms who make this a speciality will find it to their interest to show in the Exhibition electrical fittings and the manner of their application. It is especially to be remembered that the Exhibition will be visited by numbers of foreigners, and especially by many persons from our own colonies; and it is important that English electricians should not miss this opportunity of strengthening and increasing their hold on colonial trade, since it is quite certain that a strenuous effort will be made by American manufacturers to get this important source of revenue into their own hands. Another department in which the United States exhibit will certainly be deficient is that of electric railway signals. The methods on which American railways are worked do not, as is well known, require the very complete system of signalling apparatus employed in European countries; but this system is now being introduced into America, and will probably supplant the methods now in use. There is, therefore, a very favourable opportunity for manufacturers of this class of apparatus to bring themselves before the notice of American customers. Another important department which ought not to be neglected is that of electro-metallurgy. Here also English inventors will probably find it to their advantage to bring their inventions under the notice of American metallurgists. A special building in Jackson Park will be devoted to the electrical exhibits. The size of this building is 700ft. by 350ft., enclosing an area of 250,000 square feet. The space provisionally allotted to Great Britain in the building is 20,000ft. It is understood that all the buildings as well as the grounds, will be lighted at night. Applications for space in the British Section must be made upon forms to be obtained from the Secretary of the Commission, Sir Henry Trueman Wood, at the Society of Arts, John-street, Adelphi, London, W.C. They must be sent in, properly filled up, not later than February 29, 1892, and addressed to the Secretary, as above. —Yours faithfully, W. H. PREECE, Chairman of the Committee.

The Electrical Committee consists of:—Mr. W. H. Preece, the Attorney-General, Sir Frederick Bramwell, Sir Frederick Abel, Prof. W. Grylls Adams, Colonel R. T. Armstrong, Prof. W. E. Ayrton, Major Cardew, Mr. Latimer Clark, Mr. R. E. B. Crompton, Prof. W. Crookes, Prof. Dewar, Prof. Ewing, Major-General E. R. Festing, Prof. Forbes, Prof. Carey Foster, Mr. Edward Graves, Mr. Matthew Gray, Dr. John Hopkinson, Prof. Hughes, Mr. Gisbert Kapp, Mr. J. C. Lamb, Mr. William Mather, Mr. W. M. Mordey, Mr. Fletcher Moulton, Hon. Charles Parsons, Prof. Perry, Lord Rayleigh, Mr. Alexander Siemens, Mr. C. E. Spagnoletti, Prof. Silvanus Thompson, Prof. J. J. Thomson, Sir William Thomson, Major-General C. E. Webber, and Mr. Willans.

VIEWS OF ETHER WAVES AND THEIR ACTION.

BY S. TOLVER PRESTON.

There is probably nothing essentially new in the following ideas; but the point of view taken may commend itself as of practical utility for purposes of illustration.

We are well acquainted with stationary (or fixed) magnetic fields, *i.e.*, with their properties, also with rotating* magnetic fields, exemplified by the late three-phase motors. *Translated* magnetic fields, of course, show themselves when magnets or currents carrying conductors are translated. When the *electro-magnetic* theory of light is spoken of, many have, perhaps, not so clear a grasp of the nature or properties of the waves as they have of fixed magnetic fields.

May it not be simple to view waves of light and the larger waves accompanying ordinary alternating currents (in sum *all* ether waves) as travelling magnetic (*i.e.*, self-translated) fields? By "travelling magnetic fields" is meant magnetic fields (successively positive and negative) endowed with a translatory motion equal to that of light.

We may neglect, as a preliminary, the "electric displacement" or electrostatic component of the wave (situated at right angles to the magnetic), as it does not alter the principle of what we are considering; or, if we wish, of course it can be taken into account.

In this case effects precisely the same in kind would be produced as if the magnetic fields—such they really are constituting the waves—were fixed, and (conversely) objects were themselves translated with adequate velocity through these magnetic fields. This view is admittedly rough, but such conceptions are often the most useful in getting a rough-hewn image of the truth (so to speak); so that a just view of the inductive effects *in kind* may be obtained without pretending to minute accuracy as to subordinate detail. *Any* ether wave (including a wave of light) may then be regarded as consisting substantially of two contiguous—positive and negative—magnetic fields, which instead of being fixed as ordinary magnetic fields about magnets or (continuous) currents, are travelling with the velocity of light through the ether. In estimating roughly the inductive effects of light and of ether waves of whatever length, we have then only to consider those which would be produced if bodies (conducting and otherwise) were translated with adequate speed through a succession of fixed magnetic fields, alternately positive and negative. To translate bodies at the speed of light is, of course, as impracticable an achievement as the manufacture of a Carnot heat-engine; but the mode of illustration chosen may be none the less of value.

For rough illustration, a succession of fixed magnetic fields alternately positive and negative may be supposed produced by a double row of horseshoe electro-magnets, with poles facing each other, and an interval between (to allow conductors to pass across the fields), so that the magnetic fields between the opposed poles are alternately of opposite sign. Of course these fields are partly renewed (when weakened by conductors striking across the fields), at the expense of the current of the electro-magnet coils. This is not the fact with the travelling (self-translated) fields of electro-magnetic waves, although each weakened wave is immediately supplied by another. It is, it appears, an instance of difference of degree rather than of *kind* between the two cases.

For it appears, we may say, that a magnetic field can (1) either be translated with a magnet or current, or (2) it has the power, under certain conditions, of self translation (with the velocity of light) through space, when left to itself. The practical point we may lay stress on is, that whether a magnetic field translates itself (through the ether) as part of an electro-magnetic wave, or is translated in connection with a moving magnet or current, an effect substantially the same in kind as produced on conductors which the field crosses. Some practical advantage may be found in the above mode of illustration. We may note, then, that all "induction" is due to magnetic fields crossing bodies, whether these fields be carried by magnets or currents, or carry themselves, as they do in the case of waves of heat and light, waves accompanying alternate-current machines, &c.; in brief, waves of any length generated in ether, which (waves) are all the same in constitution, all consisting of travelling magnetic fields (alternately inverse).

When an alternating current is sent through a bobbin or coil of wire, it has been recently shown that it will repel a disc or ring of copper (some pounds in weight) which may even be made to float in the air, as it were, and prevented from receding, by strings; as was illustrated in *The Electrician*, March 13, 1891, p. 570. This experiment may be regarded as exemplifying also the repulsion of light, which consists equally of travelling magnetic fields, as in the above case (of the magnetic coil) only more quickly alternating. The repulsion of light or radiant heat at the sun's surface (or rather its reaction against the emitting sun) is calculably 27 grains per square foot of area. From this the total reaction against the sun due to its own radiation may be readily calculated to be 109 billion tons.*

Few realise probably that when, by the sun's agency and a "burning-glass," a hole is burnt in some substance, this is effected by the impinging of a succession of magnetic fields moving at the velocity of light, and throwing the parts (or pervading ether) of the substance into resonance, like a small-scale Hertz resonator; and with such energy that the substance is disintegrated by the alternating electric currents, which, on molecular scale, probably *themselves constitute the heat*. For we have rhythmical heat and non-rhythmical heat. The former motion seems to be an alternating electric current, which is confirmed by the fact that *electro-magnetic* waves are generated by this rhythmical motion of heat. The second form of heat, *non*-rhythmical, is quite different (perfectly irregular)—incompetent to generate waves.

Prof. Lodge, to whom many are indebted for his articles, "Modern Views of Electricity,"† expresses the view that "light is an electrical disturbance, and light waves are excited by electric oscillations" (p. 418). If this be true, of course the motion which generates *heat* waves must equally be an electrical disturbance. In further accord with this, Prof. Lodge mentions in the same article that "those short ethereal waves which are able to affect the retina, and which we are accustomed to call 'light,' may be really excited by electrical oscillations or surgings in circuits of atomic dimensions" (p. 417). But in the last of the series of articles (*Nature*, January 31, 1889) we have the remark, viz., "Light, when it falls on a conductor, excites first electric currents and then heat" (p. 321).

Assuming, of course, the "conductor" to be solid in the absence of specification, then it seems a question here whether *two* effects are excited. For the molecules of a solid, being incapable of free translatory motion, would scarcely, probably, take up that irregular *non*-rhythmical movement of heat which is the additional characteristic of liquids and gases. The rhythmical form of heat which "radiates" would doubtless alone be developed in the "conductor" on which the "light falls." If so, we have not *first* electric currents and *then* heat excited by the light, but only electric currents, which *are*, however, what we call "heat," *i.e.*, of the rhythmical kind which generate waves (viz., electro-magnetic waves which are waves of heat when short enough). The "conductor" on which the "light falls" becomes a Hertz resonator on a small scale, emitting electro-magnetic waves of the same period‡ as those which fall on it. It may even be a question whether, with an (ordinary) large-scale Hertz resonator, the so-called "heat" which accompanies the resonance may not be looked at simply as a sort of higher harmonic of the big-scale resonance, and which (small-scale resonance) also limits electro-magnetic waves. Returning for a moment to our illustration of the sun and burning-glass, suppose that, instead of impinging on a combustible substance, the magnetic fields impinge on a sheet of bright

* In regard to the particular case where a magnet rotates on its own axis, reference may be made to a Paper published by me in the *Phil. Mag.*, Feb., 1891; also other Papers, *Phil. Mag.*, Feb. and March, 1885.

* Reference may here be made to my former article in *The Electrician*, Sept. 18, 1891, "The Ether as a Power Transmitter."

† *Nature*, Aug. 30, 1888. Also now published separately as a volume, with appendices.

‡ Waves of obscure heat and waves of various periods ordinarily accompany light, of course.

Digitized by Google

silver; then disintegration is not produced by the resonance as before; but the opposing (outgoing) magnetic fields accompanying the resonance may be energetic enough to repel the entering fields, and produce nearly perfect reflection. May we not regard the reflection of light from a metal as due to the interaction or repulsion of opposing magnetic fields?

Hamburg, December, 1891.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 381.*)

THE CABLE SHIP ON REPAIRS.

1. **Speaking Apparatus.**—The position of a fault having been determined by a selection of tests the cable ship proceeds to this position, first leaving instructions upon what day and time the terminal stations are to commence keeping watch for her. When the insulation of the land line between the office

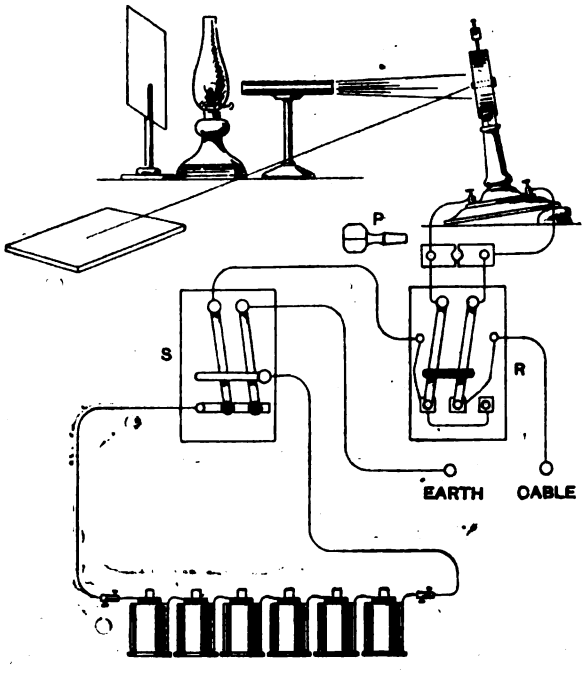

FIG. 1.—Speaking Connections.

and cable-house is perfect, watch is usually kept in the office on the syphon recorder instrument, this being most convenient; but if it is at all low the ship will not be satisfied with testing through it, and watch has to be kept at the cable-house, where the shore end of the cable is landed. In such cases a set of speaking apparatus, precisely similar to that on board ship, and usually kept at the cable-house, is connected up, as in Fig. 1. A battery of Minotti cells, in the proportion of one cell, at most, to 120 miles of cable, is joined up to the sending key S, as shown, the conductor or line of the cable is connected through the mirror instrument to one side of this key, the other side of the same being connected to the earth return of the cable. The outside sheathing of galvanised iron which protects the cable is used as the earth return. It may be mentioned in passing that the ends of cables as they are landed are, in some cases, passed through packed glands in a cast-iron joint box, and therein jointed on to insulated wires leading to the cable-house in wrought-iron pipes containing water. In this system, which is the most protective, the pipes are laid in a trench, and the joint box sunk at low-water mark. The galvanised sheathing of each cable is jointed in the box to a separate insulated wire, which is labelled in the cable-house as the earth belonging to that particular cable. In a similar manner when the cables are landed direct into the cable-house joints are made to the sheathing wires of each cable, and kept distinct as their own individual earths. It is found that unless this is done there is interference between the currents in different cables.

It is usual to fit up a small terminal board in the cable-house and bring the cables and their earths to it, where they can be joined on to the terminals of the land lines leading to the office. It is therefore a simple matter when watch for the ship is to be kept at the cable-houses to disconnect the required cable and its earth from the pair of land-line terminals to which they are joined, and connect them to the speaking apparatus as shown. A beam of light is thrown on to the mirror instrument by means of an oil lamp and lense. The latter is fixed at one end of a horizontal brass tube, and the tube is shifted until a good sharp reflected ray from the mirror is obtained. The light of the lamp should then be shielded from the eyes by a paper screen, or the lamp for this purpose may be placed in a wooden box without top. The reflected ray can either be directed horizontally so as to throw an image on a vertical white screen or the wall, or it may be directed downwards by tilting the mirror instrument as shown. For keeping watch for the ship the light should be projected on to a vertical screen, as it can then be seen from all parts of the room. The manner of titling the mirror to throw the light on the message pad, as shown in the figure, has come very generally into use where lines are worked by this instrument, the operator reading and writing down the message himself at the same time without the aid of a writer.

The mirror instrument is provided with a short-circuit piece P, which is plugged in when sending. This is a better arrangement than a two-way switch for sending and receiving, because the mirror can be proved occasionally with the sending key.

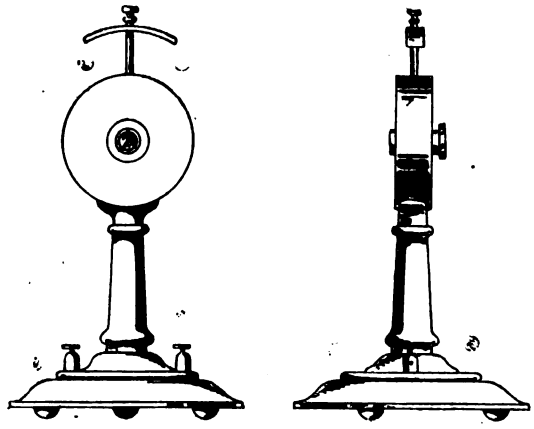

FIG. 2.—Speaking Mirror,

A reversing switch R, for reversing the signals received on the mirror, is very convenient. If the signals from the ship are reversed, all that has to be done is to turn this switch the other way. The connections of this switch are marked on the diagram, and will be easily understood. Another way of reversing the signals is to twist the tube round in which the mirror is suspended, so reversing the position of the poles of the magnet on the mirror; but this is not always a speedy way of doing it, as the controlling magnet and lense may want re-adjusting. Another way is to reverse the wires connected to the mirror instrument; but with a little practice reversed signals can be read with perfect ease, necessitating no change whatever.

In the ship's signalling connections there is generally fitted a battery commutator for changing the number of cells rapidly, to suit any length or condition of cable; but, in order to avoid delay, it is advisable to connect a shunt resistance to the mirror-instrument, which can be rapidly adjusted to make the signals a readable size directly the ship is observed calling. The wire connecting the shunt resistance to the mirror should be disconnected before the ship calls, so that the instrument is in its most sensitive state.

The mirror instrument introduced by Sir William Thomson, holds its own for simplicity against any other telegraph instrument. Although now entirely supplanted on important lines

Digitized by Google

by the syphon recorder, its use is still largely maintained. Every station has its speaking mirror to fall back on in case of one or more of the recorders failing, and its mirror for cable-house use; while on board ship it is invariably used for speaking with the shore. The instrument is a great favourite with old cable operators, and there is certainly a fascination about the noiseless movement of the spot of light, which the recorder with its revolving mouse mill cannot lay claim to. This instrument is represented in Fig. 2, and consists simply of a coil wound to a resistance of 700 to 1,000 ohms, mounted on a wooden stand. The mirror is suspended at one end of a brass tube (Fig. 3), fitting loosely into the centre of the coil, and the front cheek of the coil is splayed out to prevent interception of the reflected ray. The signals are much improved by introducing a soft iron core within the tube. The core becomes magnetised by every current received through the coil, and therefore produces greater amplitude in the signals,

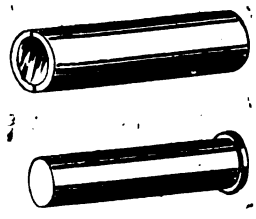

Fig. 3.—Tube and Mirror and Iron Core.

while, owing to the fact that it does not give up or reverse its magnetism as rapidly as the signalling currents pass through the coil, the signals are steadied and rounded off, a considerable advantage on short lines. This improvement was introduced by Mr. Walter Judd, of the Eastern Extension Telegraph Company, and has been found to lessen the interference of earth currents on signals. The core has a shoulder at one end to prevent it touching the mirror by entering too far in the tube, while, by adjusting the length of core within the tube the signals can be brought to any required size.

The suspension silk need not be a single fibre, but the thickness can be suited to the sensitiveness required. The silk is best fastened on by laying the mirror face downwards on a table or flat board as at M (Fig. 4), one end of the silk having been fastened down to the board by a little beeswax at A, while the other end is held in the left hand. The silk can then be held taut and slightly raised, while the mirror is shifted round so as to bring the magnet in a position at right angles to the

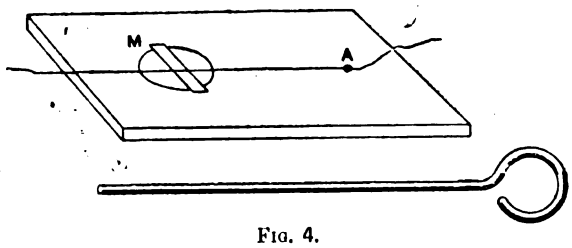

Fig. 4.

silk. By means of a light copper rod (Fig. 4) heated at the end in a spirit flame, a little melted beeswax or shellac is applied to the back of the mirror to fasten the silk down. The wax should cover the silk close up to the edge of the mirror, but not be allowed to run into the silk beyond, or it will stiffen the fibre where it should be perfectly free.

Another mode of suspending the mirror is shown in Fig. 5. To a light brass frame, with a disc, D, rigidly fixed at one end, is fixed a spring, S, and a sliding piece, P. The lower end of the silk suspension is attached to the end of the spring, and its upper end is passed over a projection on the disc, and attached to the pin A. This pin has a screw-threaded shank, which passes through a clear hole in the sliding piece P, and its position can be regulated by a nut on the shank of the pin without twisting the silk. This provides one means of adjustment, while the sliding piece P can be shifted so as to regulate the tension on the silk to any required extent, and finally fastened in position by the set screw. The spring engages in a slot in the disc, preventing it from being raised too high and decentralising the mirror. The whole, when completed and adjusted, is slipped into a brass tube, B, provided with a glass window at the end near the mirror. The tube is then slipped into the coil of the instrument. It is remarkable that the mirror-speaking instrument is so sensitive to cable signals when the suspension fibre is fastened top and bottom, and there is only about

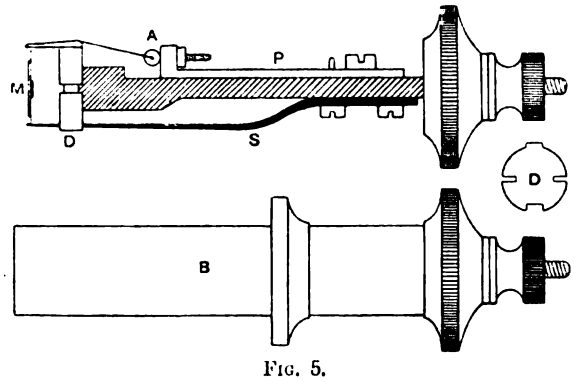

Fig. 5.

one-sixteenth of an inch of fibre above and below the mirror free to turn. The first experiments were with long fibres; but soon after the completion of the 1866 Atlantic Cable Mr. Graves, the superintendent at Valentia station, together with Mr. T. E. Weatherall, carried out a series of experiments starting with fibres 2in. long each side of the mirror, and found that the instrument retained its sensitiveness as they reduced the length of fibre step by step till a length of only $\frac{1}{16}$in. was found to be necessary for good sharp signals.

(To be continued.)

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 19th.

3 p.m. Inauguration of the "William Siemens" Electrical Laboratory, at King's College. By Sir William Thomson, P.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Micro-Organisms in their relation to Chemical Change." By Prof. Percy F. Frankland, F.R.S.

SATURDAY, February 20th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Matter at Rest and in Motion." By Lord Rayleigh, F.R.S.

MONDAY, February 22nd.

LONDON CHAMBER OF COMMERCE.

2.30 p.m. Special General Meeting at Botolph House, Eastcheap: "To consider the general position of the Commercial Community in regard to the Telephone Service of London and the Telephone Bills now before Parliament." Sir A. K. Rollit, M.P., in the Chair.

TUESDAY, February 23rd.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be read with a view to discussion: (1) "The Bishop Rock Lighthouses." By W. T. Douglass, M.Inst. C.E. (2) "The Illumination by Gas of Tory Island Lighthouse, Co. Donegal." By David C. Salmond, Assoc.M.Inst.C.E. The Meeting will be adjourned at 9 p.m., when the President and Council will hold a Reception in the Libraries.

WEDNESDAY, February 24th.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Ancient and Modern Art Pottery of Japan." By Ernest Hart.

THURSDAY, February 25th.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

FRIDAY, February 26th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read: (1) "On Modes of representing Electromotive Forces and Currents in Diagrams." By Prof. S. P. Thompson, F.R.S. (2) "On the Flexure of Long Pillars under their own Weight." By Prof. Maurice FitzGerald, M.B. (3) "On Choking Coils." By Prof. J. Perry, F.R.S.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "Optical Projection." By Sir David Salomons, M.A.

ublished every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed "Coutts and Co." All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

NOW READY.

STEEL-PLATE PORTRAITS

Of W. H. Preece, F.R.S.; Michael Faraday (out of print); Sir John Pender, K.C.M.G.; Sir William Thomson, F.R.S. (Past-President of the Institution of Electrical Engineers); C. H. B. Patey, C.B. (Late Secretary of Telegraphs, G.P.O.); Dr. John Hopkinson, F.R.S. (Past-President of the Institution of Electrical Engineers); Dr. Oliver J. Lodge, F.R.S., Prof. William Crookes, F.R.S. (Past-President of the Institution of Electrical Engineers); Willoughby Smith (out of print); Prof. von Helmholtz, and Prof. W. E. Ayrton (President of the Institution of Electrical Engineers), have been issued as Supplements to "THE ELECTRICIAN."

A few Copies of these admirably-executed Steel Engravings can be supplied price 1s. each, post free on roller, 1s. 2d. Or framed in neat Black Pillar or Brown Ornamental Frames, price, 4s. 6d, carriage paid (U.K.)

ERRORS IN TELEGRAMS.

The epidemic of correspondence relating to the shortcomings and misdeeds of the telegraph service has, this winter, been of unusual length and severity. If to err is human—and the telegraph is very human in that respect—to grumble is also human; and when free outlet for it is offered in the daily newspapers, no wonder the grumblers grow more numerous every year. For telegraphic errors, following the law of averages like other things, increase with the increase of telegrams, although their relative proportion may remain unaltered. We all have our experience of blunders in telegrams, and know how exasperating they are; but we know too that we get many more telegrams than we did formerly when they were much dearer, and not free from error even then. Still the fact is none the less vexatious that telegrams are shockingly mutilated at times, and that minor and trifling errors are as common as flies in treacle. We are therefore not sorry to see this long string of complaints made public; for it will have the effect, no doubt, of reducing some of the avoidable errors, which, if of no great importance, cast discredit on the administration. This class of error, we often suspect, is due to slovenly writing in the offices, and to the absence of a little common sense. These are defects that might be remedied. Then, again, the speed of signalling is said to be a fruitful source of error. In one of the very few letters published on "the other side" a telegraphist complained that the sending was generally too fast—meaning faster than the receiving

Digitized by Google

operator can read correctly. If this is true to any great extent probably some check could be put upon a practice so risky, even though the public would lose something in the way of speed. Complaints on the score of delay are comparatively rare. Perhaps there would be none the more if the signalling were a little slower.

As regards unavoidable or venial errors, they are largely attributable, on the one hand, to electrical or mechanical failures, and on the other to misreadings of the text. Of the former it would seem that everything has been done that ingenuity, science and money can do to make the appliances and wires as perfect as they are capable of being. But they have their weak points at the best, and become less and less reliable as the high speeds are increased. And this is true, also, of the human part of the machinery; for there is, no doubt, a rate of working beyond which the eyes and ears and hands cannot be always trusted. The public have got their cheap telegrams, and in such abundance that they must be despatched with dangerous rapidity. The public ought to be tolerant, therefore, of mistakes due to these causes. Misreading of the text is more often the senders' fault than the operators'. If the public would give themselves the trouble to write legibly, and word their messages with some regard to the possibilities of their being misunderstood, there would be very few complaints under this head. Business firms do attend to these matters, and are sending telegrams all the day long; but the general public do not, and in the aggregate they probably send most of the telegrams that occupy the wires. Anybody who has experience of how the general public use their pens can form some idea of what the telegraphist has to decipher in the way of handwriting, and this when the signalling is being done at top speed. As often as not the context gives no more clue to the meaning than the coded words of a cablegram; for your general public have learnt how to cut down their missives to the scrappiest and most disjointed sixpennyworth possible, with the result that unless it is written plainly, which is seldom the case, it is sure to be signalled wrongly.

The class of persons just referred to were foremost among the complainants in the newspapers; indeed, we do not remember seeing the signatures of any business firms, although individually they send and receive by far the greatest number of telegrams. This fact would seem to support our view that compared with the gross number of messages, the mistakes in them are not extravagantly numerous. Business men, however, have the advantage of corresponding with business places, where, of course, there are appliances and operators of a first-rate order. Obviously this is not the case everywhere, and never can be the case. The non-business part of the community, whose miscellaneous telegrams are destined for suburban villas, small provincial towns, and country villages, far from the madding crowd, have therefore to put up with an inferior service. Nobody can reasonably complain of this, unless it be the Post Office itself, who, by stress of public demands, have had to extend the system far beyond its paying capacity, and, for other reasons, far beyond the possibilities of maintaining a uniformly high efficiency. Good telegraphists are made by large experience—experience which cannot be had in the minor offices of the service.

There remain only those errors which are due to the operators themselves, whether experienced or inexperienced. The best of them blunder, oftener, probably, than we hear of. So far as we know there is no check upon them, except public complaints; and as all recording instruments have gone out of fashion it is no longer possible to fix the blame upon the offending party. This is one of the evils attendant upon high speeds of signalling, necessitated by the enormous increase of work. When the tariff was about to be cheapened to sixpence we predicted that though it would be nicer for the pockets of senders it would be nastier for their telegrams. The only remedy possible would be a vast augmentation of the number of wires, and a general slowing down of the signalling; but this would be far from nice for the pockets of the taxpayer. On the whole, therefore, we are inclined to think that the benefits of a cheap system of telegraphy must be accepted as a set-off against the inherent defects of such a system, except as regards those imperfections which careful supervision can cure. The public may not accept this view of the case, but in more ways than one they have a remedy in their own hands. The *Standard* tells them that their telegrams are always of vital importance, and that nobody is so foolish as to spend sixpence when the matter is not urgent. It would be just as true to say that nobody takes a penny omnibus who can walk, or that nobody would spend sixpence upon a drink unless dying of thirst. The *Standard's* statement is ludicrously wrong. If all telegrams were withheld that could be just as easily served by letter or by hand, the pressure on the wires would be appreciably diminished. For the rest, if the senders would take a little more pains themselves, they would have much less cause to complain of the telegraphists.

THE DETERMINATION OF CURRENTS IN ABSOLUTE ELECTRO-MAGNETIC MEASURE.

BY G. F. C. SEARLE, M.A.

(Continued from page 348.)

§ 62. **General Considerations.**—In practical electrical science we meet with many quantities of widely varying natures, such as capacities of condensers, coefficients of self and mutual induction, resistances of coils, and so on; and we frequently desire to know the values of these quantities in terms of some units which are known and recognised by other experimenters. The progress of electrical science, and the recognition and appreciation of the great principle of the conservation of energy, have led electricians to understand that all electrical quantities can be ultimately referred to the units of length, mass, and time. When once the connections between electrical and dynamical quantities have been clearly perceived, and it has been determined to work upon a system of derived units which introduces the smallest possible number of numerical factors into the equations, we are no longer free in our choice of electrical units. (*See* § 3.) There are two alternatives before us. We may *either* have a free choice of electrical "standards," and, for instance, define the unit of resistance as that of a metre of mercury of one square millimetre section, and the unit of E.M.F. as that of a standard Clark cell; *or* we may have a rational dynamical system of units with a minimum of numerical factors. Units arranged according to the first plan are apparently more easily understood, if we may judge by the statements made by elementary students and by some text-books. But in the minds of all who are qualified to judge of these matters, there is no doubt whatever but that the second plan is incomparably superior to the first.

§ 63. **Heaviside's System.**—The dynamical system of electro-magnetic units at present in vogue frequently introduces the remarkable quantity 4π in a way which seems to be regarded by many people as extremely mysterious. We are also informed in many quarters that this 4π is a great stumbling-block in the way of *practical* electricians. Mr. Oliver Heaviside* has shown us where the 4π takes its origin, and has proved that matters could be considerably simplified by defining a unit magnetic pole to be such as acts on an equal pole at 1cm.

* *The Electrician*, October 16, 1891.

Digitized by Google

distance with a force 4π dynes, and by making some other changes of a similar nature. The magnetic force inside a solenoid reckoned in this new system would be simply the product of the strength of the current by the number of turns of wire per centimetre length of the coil. If this new system ever comes into use no new determinations of the B.A. Units or other electrical "standards" will be requisite; it will only be necessary to multiply their values by some power of (4π). Whether or not this would be jumping out of the frying-pan into the fire I do not pretend to decide. At any rate, Mr. Heaviside's system merits very careful consideration, in that it gives the very fullest expression to Faraday's grand idea of "lines of force." Dr. H. Hertz,* who has closely followed Mr. Heaviside in his treatment of the equations of the electro-magnetic field, makes use of definitions which, as far as I understand them, appear to be equivalent to those in common use. We shall not, however, pursue this subject any further, but return to the system employed at present.

§ 64. **Electrical "Standards."**—Since we have given up our free choice of units in return for the advantages of a dynamical system, we see that there are, from this point of view, only three things which have any title to be called Standards, viz., the "Mètre des Archives," the "Kilogramme des Archives" and the "Mean Solar Second." (*See* § 2.) The general problem of electrical measurement is the determination in C.-G.-S. measure of some electrical quantity. But even if we have the necessary skill, the great amount of labour involved precludes our making a *direct* determination. We therefore seek for some so-called *standards*, whose values in C.-G.-S. measure can be found with great accuracy by trustworthy experimenters, so that we may be able to base our measurements upon them, and use them as a kind of half-way house. Similar wants make themselves felt even in ordinary mechanics. Thus, when we wish to determine the density, *i.e.*, the mass in grammes of a cubic centimetre of any substance, say copper, we do not make of the copper a cube whose dimensions we can ascertain by comparison with a standard scale, and whose mass we can find by the aid of some standard weights, but we determine the ratio of the density of the copper to the density of water by the aid of the hydrostatic balance. The labours of scientific men have enabled us to find the numerical value of the density of water in tables of physical constants, and thus we are able to calculate the density of the copper. Moreover, a determination of density made in this way by an experimenter of average skill would probably be more accurate than a *direct* determination by the same person, and would certainly be much more expeditious. The really difficult part of the work has been done perhaps years previously by scientific men of the highest attainments, and our belief in their skill and good faith and in the immutability of the properties of water is such that we accept their results and use them in our calculations.

§ 65. **Choice of "Standards."**—The same principles hold good in the case of electrical science, and thus it becomes of importance to decide what electrical quantities shall have their values determined with all possible accuracy in "absolute" measure, so as to be available as "standards" to the electrical world at large. The permanent character and the practical convenience of a properly constructed resistance coil caused the resistance of such a coil to be the first electrical quantity which was determined with any accuracy. The first elaborate "absolute" measurement of resistance in this country was made by the Committee of the British Association in the years 1863, 1864; and as the result of the work of that Committee the British Association Units were issued as "standards."† Later experimenters have shown that the resistances of these coils are not exactly what they were intended to be, and have redetermined their resistances with great accuracy.

Although an accurate knowledge of the resistances of coils is a very great step, and one which enables us to determine in absolute measure the values of several of the electrical quantities, such as, for instance, capacities and coefficients of induction; still there are many measurements which cannot be made by the help of "standards" of resistance alone. It appears, however, that all the electrical quantities can be determined by the aid of *two* "standards." We have chosen the resistance of a certain coil as one of these standards, and now have to decide upon the second "standard." The two quantities from which the choice can be most conveniently made are a current and an E.M.F. Neither of these quantities can, however, be embodied in a material form of the same permanence as a resistance coil, and, in fact, a current cannot be embodied in any material form at all. In the electro-magnetic scheme of units, the unit current is the first *electrical* quantity which is defined; so that it would seem natural to adopt some manifestation of a current as a standard, especially as in any practical method of determining E.M.F. in "absolute" measure, we have to make use of this definition of unit current. But since an electric current is not a thing which can be kept under lock and key, like a resistance coil or a standard voltaic cell, we are obliged to have recourse to some one of the effects of the current. One of these effects, which is most convenient for purposes of measurement, is the electrolytic effect, and this has the additional recommendation that it is proportional to the strength of the current in electro-magnetic measure, as has been shown by Faraday and by Lord Rayleigh. A current is passed through a voltameter charged with silver nitrate or copper sulphate, and, by means of a carefully-constructed electro-magnetic meter or balance, its strength is determined in absolute measure; and in this way a relation is established between the rate of deposition of silver or copper, in grammes per second, and the strength of the current. When once this relation has been accurately established, silver or copper voltameters may be employed in the measurement of currents. It was the object of Lord Rayleigh's work on the "Electro-chemical Equivalent of Silver"* to embody, in a numerical statement, this relation in the case of silver. Strictly, this method is applicable not so much to an electric *current* as to an electric quantity. Lord Rayleigh points out that we might in a more direct way embody our knowledge of unit current in the numerical statement of the rotation of the plane of polarisation of sodium light, which traverses a long column of bisulphide of carbon, encircled by the current a stated number of times.

As regards the choice of *silver*, Lord Rayleigh remarks† that there is not much room for difference of opinion. "The difficulties to be overcome in the case of a water voltameter are much greater. Copper is, indeed, employed in ordinary laboratory practice and for commercial purposes; but it is decidedly inferior to silver both on account of its tendency to oxidise when heated in the air, and also because it changes weight in contact with copper sulphate without the passage of an electric current. Silver, on the other hand, seems to be entirely unaffected by contact with neutral solution of the nitrate." For information as to how far the disadvantages attaching to the use of copper may be overcome, the reader is referred to the work of Mr. Thomas Gray, in connection with the standardising of Sir William Thomson's Electrical Measuring Instruments. (See *Phil. Mag.*, Nov., 1886.)

JOHNSTONE ELECTRICAL CONDUIT.

Among the various systems of underground conduits for electrical conductors which were described in Mr. J. B. Verity's Paper before the Institution of Electrical Engineers in April, 1889, was that known as the Johnstone conduit, which has been introduced into this country by the International Electric Subway Company, of 39, Victoria-street, Westminster. This conduit was described and illustrated in *The Electrician*, Vol. XXII., page 715; and we give herewith some further details. It is a thoroughly American invention, consisting as it does of very ingeniously designed iron castings of various shapes, which fit together, and enable conduits, manholes, branches, and outlets to be built up and constructed with a very little expenditure of low-class labour. No less than 111 miles of this conduit are at the present time in use in New York, Philadelphia, and other American cities.

The conduit consists essentially of two cast-iron troughs, one forming a cover for the other (Figs. 1 and 2). The

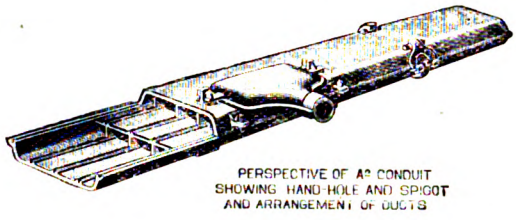

FIG. 1.

dimensions vary considerably, the internal capacity ranging between 233 square inches and 4½ square inches. The larger sizes occupy about the same space as the iron troughs used by the St. James's and Pall Mall Supply Company. The joints are not butt joints, as is usual in most systems, but the upper and lower sections, made in 5ft. lengths, are arranged so as to break joints, and they are clamped together by an ingenious arrangement of keys and wedges. Plumber's putty is relied upon to keep these conduits dry, and this material is laid in all the grooves and abutting ends. We understand that in America this has proved to be sufficient, even in the low-lying parts of New York; but it is well known that in London and elsewhere in this country thoroughly well screwed-up joints, made with red lead, cannot always be relied upon, and the condensation of moisture in the conduit itself is no small difficulty. For the purpose of

FIG. 2.

remedying this, English engineers have had to pay careful attention to drainage; but we understand that no special arrangements are at present provided in the Johnstone system. This conduit is intended for protecting insulated cables, and is not arranged for carrying bare conductors. Shelves are provided, and partitions are arranged on these, in order to keep the conductors in position, but when repairs are necessary the upper section can be removed. As many shelves and partitions as necessary may be slid out, and thus the defective cable may be repaired, without disturbing the others. The upper sections are provided with an attachment for handholes, as shown in fig. 1; this can be placed in front of the house at the time the conduit is laid, or any section may be replaced by one containing a handhole. All castings for branches are arranged with well-rounded corners to prevent chafing of the cables.

Large cast-iron manholes are provided, for the purpose of distributing, and for access to the important parts and branches. It is characteristic of the American practice to construct in cast iron that which is made by most English engineers in brickwork laid in cement. The manhole, of which we give a vertical section (Fig. 3), is built up of a number of plain segments; but any one of these may be replaced by a segment containing an outlet for a conduit, as shown in Fig. 4. One of these manholes has been put together at the offices of the International Electric Subway Company, where we have examined it. There is plenty of room for work inside, but it might often be difficult to find space for it among the pipes under the street.

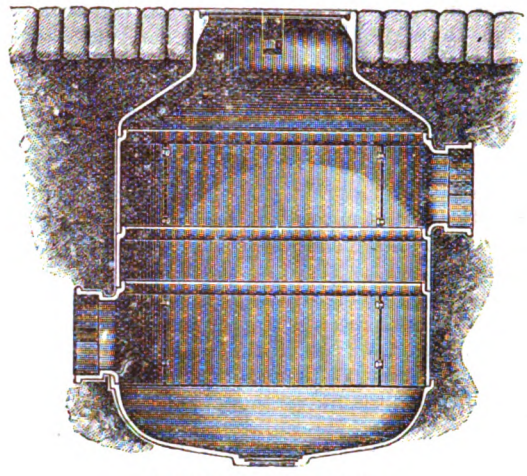

FIG. 3.

The conduit can be laid very rapidly, and the great facilities for interchangeability of all the parts is an important feature. The sections are so arranged that the inside is perfectly smooth, allowing every facility for drawing in the cables. The Subway Company, who appear to be very much averse to the use of lead-covered cables, give an illustration in the pamphlet which they issue of an ingenious method of drawing in. A vertical shaft is fitted, dropping into a step bearing, in the centre of the manhole, and rising three or four feet above the level of the street, and is provided with capstan bars. A barrel is mounted on this spindle at the level of the conduit, and the drawing-in rope is

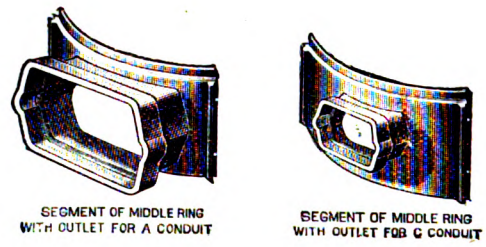

FIG. 4.

wound upon this. As in many other American engineering inventions, this one distinctly aims at being a "system." Whether this will find favour with English electrical engineers cannot be decided by any but those who have to deal practically with the laying and maintenance of conductors below our streets. The samples at the office of the Company are well worth inspection.

Institution of Electrical Engineers.—A students' meeting was held on Friday, the 12th inst., at the Library of the Institution, Mr. James Swinburne presiding. The following students were elected to serve on the Committee for 1892:—Messrs. T. H. Minshall, H. B. Little, C. C. Wharton, R. L. Griffin, A. T. Weightman, S. B. Roth, and H. C. Haycraft, hon. sec. Mr. H. B. Little read a Paper, "Notes on Electroplating." The next meeting will be held on the 26th inst., when Mr. C. Courtenay Wharton will read a Paper on "Some Details of House-wiring."

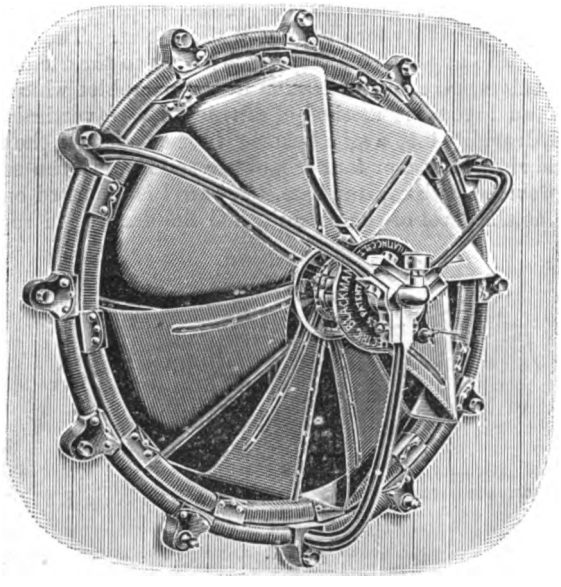
THE ELECTRIC BLACKMAN FAN.

One of the difficulties in the application of electric motors, especially small ones, to mechanical work, is the high speed which it is necessary to employ if reasonable efficiency be desired; and belting or other gearing when applied to half or quarter horse-power motors introduce mechanical losses which may far exceed the electrical waste. Various motors have been tried in connection with the well-known Blackman fan, but the motor has had to be belted down, or run slow, or else the fan has been driven so fast that much of the work has been expended in churning up the air, and has been dissipated in eddies.

There are many obvious advantages in driving a ventilating fan by electricity, as the power required is small, and the fans often have to be distributed in various parts of a building where no mechanical power is being used. In order to drive the fans with economy and at the speed which experience has shown to be the best, a motor has been arranged surrounding the fan itself. The large circumference of the armature enables the speed of rotation to be kept down; and although there appear to be several theoretical objections to the principle, the figures which we have received appear to amply justify the use of this kind of motor. Even if the consumption of electrical energy were the same as in an ordinary small motor, there are several mechanical advantages which are worth mentioning; there is no side pull on the bearings, the wear of the shaft is very largely reduced, and there is little friction other than that due to the end thrust. It is possible by careful arrangement of the parts to reduce even this by the pull of the magnets on the armature. Another advantage is that there is no motor to obstruct the direct flow of the air. The arrangement, which is due to Mr. Watel, of the Blackman Ventilating Company, is clearly shown in the illustration. Both



Electric Blackman Fan.

the armature and the magnet rings are composed of soft iron, well laminated. It is easily fitted up for temporary work, and the smaller size may be connected by an ordinary flexible wire to the nearest lamp socket. As in ordinary multipolar dynamos, the sections of the ring armature are so connected to a commutator that only two brushes are required. This motor, consisting of two large rings, the outer with internal, and the inner with externally projecting poles, closely resembles the motor constructed by Elias of Amsterdam, in 1842. Over 20 of these electric fans were employed at the Frankfort Exhibition, and they are at work at the Crystal Palace. Of the real efficiency of the motor we have at present no information of a scientific character; and when we inform our readers that a two-foot fan, running at 450 revolutions, requires ¼ H.P. to drive it mechanically, but only 100 to 140 watts to drive it electrically, it need not be assumed that the efficiency of the motor is from 133 to 186 per cent. The fact is that electrical energy can be supplied in the most advantageous manner possible, while any mechanical driving must entail some waste, and where belts are used at such a high speed this may be very considerable. These motors have been generally run at about 70 volts; 1½ amperes is sufficient for the 24in. fan, which delivers about 2,700 cubic feet of air per minute, through a duct 2ft. in diameter.

A slow-running motor may some day be a very important desideratum, and we hope that the Blackman Ventilating Company will make a careful test of one of these motors with the blades of the fan removed, since it is impossible to accurately measure the power developed by the fan, unless by a comparison with an independent test of the same fan driven mechanically; and, as we have already pointed out, such mechanical driving must, in most cases, entail serious losses in being transmitted to the shaft of the propeller.

THE RUMOURED AMALGAMATION OF THE EDISON AND THOMSON-HOUSTON COMPANIES.

[COMMUNICATED.]

The rumoured amalgamation of the Edison General Electric and Thomson-Houston Companies in the United States, if true, will be viewed with alarm alike by competitors, local supply companies, and electric railways. To the mind of the general reader such monopolies as the Standard Oil and Western Union Telegraph Company will be at once recalled. Backers of the deal are doubtless past masters in the most approved methods of American "combine." The pooling of interests such as these would be the virtual crowding to the wall of the few independent manufacturers of dynamo-electric machinery; not to speak of the severe blow which would be administered to the Westinghouse Company, and with it indirectly to the extension of alternating-current central stations upon anything but a small scale. The capital of the Edison Company at the present time is about $12,000,000, and of the Thomson-Houston about $10,000,000. So much for the two parent companies proper. The latter also controls or owns the Fort Wayne Electric Company, which manufactures alternating apparatus, and has a capital, the precise figure of which is not known; but is, nevertheless, large; the Brush Electric Company, with an arc, incandescent, and railway system (Short); besides the Excelsior, Schuyler, and a few other small concerns. Local Supply Companies include those which not only supply light and power, but also control the rights of exclusive sale in many cases for the surrounding districts, the parent or manufacturing company in each case owning a preponderating voice in the management in return for the advantages accrued. When it comes to be considered that no cities with any pretensions to size are without a supply company on a large or small scale, a rough estimate may be formed of the vast influence wielded by parent companies, especially when it is stated that outside the Edison and Thomson-Houston no company does a large business except the Westinghouse, and this Company on a much smaller scale than the other two.

Let us take a cursory glance at the status of the local companies in the city of New York. There the sole right to construct and lease subways has been granted to what is known as the Consolidated Telegraph and Electrical Subway Company. This is a pocket interest of the Edison Company. The subways are admitted to be very badly constructed, and difficult to free from illuminating and other gases; but all companies are obliged to lease the ducts at extravagant figures or go out of business. In the meantime the Edison Illuminating Company have constructed from about 58th-street right down to the Battery a network of most excellently-constructed tubes of the regular pattern, the three-wire system of course being used, and so laid down as to allow of all the stations being connected together. This allows of all the stations but one being shut down during the hours of light load. It may not be generally known that all overhead wires are now forbidden, with the

Digitized by Google

exception of some of the outlying avenues and districts, where, so far, no subways exist. The local Edison Illuminating Company practically monopolises all the incandescent lighting in the City.

This sample of what is done in Gotham may be fairly construed to represent what takes place in other cities, great and small, in the United States, if not in the Dominion also. Perhaps we may be allowed to digress for one minute to examine into a small "sideplay," which possibly may shed light and explain the means by which the franchise, mentioned above, was obtained. The late Mr. Michael Flynn, of Tammany Hall fame, enriched himself by a commission levied on every length of iron pipe used in the construction of the subways. Doubtless, many another municipal lamb received a *quid pro quo*, which was substantial if not regular.

In the matter of the local railway (tramway) companies the very great majority are owned by either the Edison or Thomson-Houston Companies, or their "sideshows." Such representative roads as the West End of Boston, the Minneapolis and St. Paul, the Cincinnati, Denver, Milwaukee, and other great and small Companies, operate the apparatus of one or other of these two Companies. In fact, fully 80 per cent. of all the electric traction is done by the two above. The isolated lighting business must again amount to a figure, of which people in this country have only a small conception. The value of business done by the Edison Company in the year 1889-1890 was $15,000,000. In 1890-1891 the number of hands in the Schenectady Works of this Company was increased from something like 1,800 to 3,800, so that an estimate may be figured what business was transacted in the latter year. The Thomson-Houston Company have likewise made corresponding increases in their facilities.

We shall now briefly state a few of the patents which would be included in this deal :—Thomson and Brush's patents for arc lighting generators, the Edison glow-lamp patent, Brush's patents (the only valuable ones) on storage batteries, Sprague's railway patents, Van Depoele's ditto, Edison's underground system and three-wire method of distribution, and Slattery's patent for the distribution by transformers in multiple. The above combination will doubtless effect great reductions in the cost of manufacture, but not necessarily in the selling price of apparatus.

These rumours will at once call to mind the pooling, in 1887, of the Westinghouse and Thomson-Houston interests, which deal was proclaimed by loud trumpet blasts. This well-matched team pulled together with as much grace as a thorough-bred mare and a grey mule might be expected to display when hitched up to a band waggon. The result of this partnership was the annulment of the contract in 1888, so that if the latest rumour is true it may be fairly conjectured that something more than a mere combination will be necessary to ensure any permanency.

In conclusion, it may be stated that Mr. W. R. McKee, son-in-law of the President of the United States, is intimately connected with the Thomson-Houston Company, so that the rumour may possibly point to a temporary arrangement for grabbing all the light and power franchises in Chicago during the World's Columbian Exposition.

THE WORK OF JOSEPH HENRY.*

In every well-ordered library stand the volumes of Silliman's *Journal of Science*, the chief repository of the labours of the pioneers, the scientific investigators of our earlier years. If it has been pleasant to dwell in our own words upon Henry's experiment which answered the great question : Can Magnetism produce Electricity? let us now allow him to tell his own story; let us find in the *Journal* the Paper we saw him hurriedly preparing for its pages in those last days of June, after reading the brief notice which told him of Faraday's success. It is dated July, 1832. We give it entire, breaking the thread of the narrative here and there for comment :—

ON THE PRODUCTION OF CURRENTS AND SPARKS OF ELECTRICITY FROM MAGNETISM.*

Although the discoveries of Oersted, Arago, Faraday and others, have placed the intimate connection of electricity and magnetism in a most striking point of view, and although the theory of Ampère has referred all the phenomena of both these departments of science to the same general laws, yet until lately one thing remained to be proved by experiment, in order more fully to establish their identity, namely, the possibility of producing electrical effects from magnetism. It is well known that surprising magnetic results can readily be obtained from electricity, and at first sight it might be supposed that electrical effects could with equal facility be produced from magnetism ; but such has not been found to be the case, for although the experiment has often been attempted, it has nearly as often failed.

It early occurred to me that if galvanic magnets on my plan were substituted for ordinary magnets, in researches of this kind, more success might be expected. Besides their great power, these magnets possess other properties, which render them important instruments in the hands of the experimenter ; their polarity can be instantaneously reversed, and their magnetism suddenly destroyed or called into full action, according as the occasion may require. With this view I commenced last August,† the construction of a much larger galvanic magnet than, to my knowledge, had before been attempted, and also made preparations for a series of experiments with it on a large scale, in reference to the production of electricity from magnetism. *I was, however, at that time accidentally interrupted* in the prosecution of these experiments, *and have not been able since to resume them until within the last few weeks,*‡ and then on a much smaller scale than was at first intended. In the meantime, it has been announced in the 117th number of the *Library of Useful Knowledge*, that the result so much sought after has at length been found by Mr. Faraday, of the Royal Institution. It states that he has established the general fact, that when a piece of metal is moved in any direction, in front of a magnetic pole, electrical currents are developed in the metal, which pass in a direction at right angles to its own motion, and also that the application of this principle affords a complete and satisfactory explanation of the phenomena of magnetic rotation. No detail is given of the experiments, and it is somewhat surprising that results so interesting, and which certainly form a new era in the history of electricity and magnetism, should not have been more fully described before this time in some of the English publications. The only mention I have found of them is the following short account from the *Annals of Philosophy* for April, under the head of "Proceedings of the Royal Institution."

So far, Henry's Paper is introductory. It now gives two series of experiments, *the one made before, the other after* seeing the brief account of Faraday's result. In the first series we find the experiment we have sketched, and if made before April, 1832, the date of the notice, then, before August, 1831, when Henry's experiments stopped.

Before having any knowledge of the method given in the above account, I had succeeded in producing electrical effects in the following manner, which differs from that employed by Mr. Faraday, and which appears to me to develop some new and interesting facts. A piece of copper wire, about 30ft. long and covered with elastic varnish, was closely coiled around the middle of the soft iron armature of the galvanic magnet, described in vol. xix. of the *American Journal of Science*, and which, when excited, will readily sustain between 600 and 700 pounds. The wire was wound upon itself so as to occupy only about one inch of the armature, which is seven inches in all. The armature, thus furnished with the wire, was placed in its proper position across the ends of the galvanic magnet, and there fastened so that no motion could take place. The two projecting ends of the helix were dipped into two cups of mercury, and there connected with a distant galvanometer by means of two copper wires, each about 40ft. long. This arrangement being completed, I stationed myself near the galvanometer and directed an assistant at a given word to immerse suddenly, in a vessel of dilute acid, the galvanic battery attached to the magnet. At the instant of immersion, the north end of the needle was deflected 30deg. to the west, indicating a current of electricity from the helix surrounding the armature. The effect, however, appeared only as a single impulse, for the needle, after a few oscillations, resumed its former undisturbed position in the magnetic meridian, although the galvanic action of the battery, and consequently the magnetic power, was still continued. I was, however, much surprised to see the needle suddenly deflected from a state of rest to about 20deg. to the east, or in a contrary direction, when the battery was withdrawn from the acid, and again deflected to the west when it was re-immersed. This operation was repeated many times in succession, and uniformly with the same result, the armature the whole time remaining immovably attached to the poles of the magnet, no motion being required to produce the effect, as it appeared to take place only in consequence of the instantaneous development of the magnetic action in one, and the sudden cessation of it in the other.

* Abstract of Article III. of a series by Miss Mary A. Henry, appearing in the *Electrical Engineer* of New York. For abstracts of Articles I. and II. see *The Electrician* January 29th and February 5th.

* From Silliman's *American Journal of Science*, July, 1832 ; Vol. XXII. pp. 403—408.

† That is, August, 1831, since the Paper was published July 1, 1832.—M. A. H.

‡ The last two weeks in June (see latter part of the Paper) an interval of ten weeks between the cessation and resumption of the experiment.—M. A. H.

Digitized by Google

Notice here Henry's instant recognition of the fundamental conditions of the phenomenon.

This experiment illustrates most strikingly the reciprocal action of the two principles of electricity and magnetism, if indeed it does not establish their absolute identity. In the first place, magnetism is developed in the soft iron of the galvanic magnet by the action of the currents of electricity from the battery, and secondly, the armature, rendered magnetic by contact with the poles of the magnet, induces in its turn currents of electricity in the helix which surrounds it; we have thus as it were electricity converted into magnetism and this magnetism again into electricity.

Another fact was observed which is somewhat interesting inasmuch as it serves in some respects to generalize the phenomena. After the battery had been withdrawn from the acid, and the needle of the galvanometer suffered to come to a state of rest after the resulting deflection, it was again deflected in the same direction by partially detaching the armature from the poles of the magnet to which it continued to adhere from the action of the residual magnetism; and in this way, a series of deflections, all in the same direction, was produced by merely slipping off the armature by degrees until the contact was entirely broken. The following extract from the register of the experiments exhibits the relative deflections observed in one experiment of this kind:

At the instant of immersion of the battery, deflection				40° west.
At the instant of emersion	„	„	„	18° east.
Armature partially detached	„	„	„	7° „
Armature entirely detached	„	„	„	12° „

The effect was reversed in another experiment, in which the needle was turned to the west in a series of deflections by dipping the battery but a small distance into the acid at first, and afterwards immersing it by degrees.

From the foregoing facts, it appears that a current of electricity is produced for an instant, in a helix of copper wire surrounding a piece of soft iron, whenever magnetism is induced in the iron; and a current in the opposite direction when the magnetism ceases; also that an instantaneous current in one or the other direction accompanies every change in the magnetic intensity of the iron.

The Paper now proceeds to give the series of experiments, made in the last weeks of June, 1832, *after* seeing the brief notice of April of Faraday's results.

Since reading the account before given of Mr. Faraday's method of producing electrical currents, I have attempted to combine the effects of motion and induction; for this purpose a rod of soft iron, ten inches long and one inch and a quarter in diameter, was attached to a common turning lathe, and surrounded with four helicos of copper wire in such a manner that it could be suddenly and powerfully magnetised while in rapid motion by transmitting galvanic currents through three of the helices; the fourth, being connected with the distant galvanometer, was intended to transmit the current of induced electricity; all the helices were stationary, while the iron rod revolved on its axis within them. From a number of trials in succession, first with the rod in one direction then in the opposite, and next in a state of rest, it was concluded that no perceptible effect was produced on the intensity of the *magneto-electric* current by a rotary motion of the iron combined with its sudden magnetisation.

The same apparatus, however, furnished the means of measuring separately the relative power of motion and induction in producing electrical currents. The iron rod was first magnetised by currents through the helices attached to the battery, and while in this state one of its ends was quickly introduced into the helix connected with the galvanometer; the deflection of the needle in this case was seven degrees. The end of the rod was next introduced into the same helix while in its natural state, and then suddenly magnetised; the deflection in this instance amounted to 30 degrees, showing a great superiority in the method of induction.

The next attempt was to increase the *magneto-electric* effect while the magnetic power remained the same, and in this I was more successful. Two iron rods, six inches long and one inch in diameter, were each surrounded by two helices, and then placed perpendicularly on the face of the armature, and between it and the poles of the magnet, so that each rod formed, as it were, a prolongation of the poles, and to these the armature adhered when the magnet was excited. With this arrangement a current from one helix produced a deflection of 37 degrees; from two helices, both on the same rod, 52 degrees; and from three, 59 degrees; but when four helices were used, the deflection was only 55 degrees; and when to these were added the helix of smaller wire around the armature, the deflection was no more than 30 degrees. This result may, perhaps, have been somewhat affected by the want of proper insulation in the several spires of the helices; it, however, establishes the fact that an increase in the electric current is produced by using at least two or three helices instead of one. The same principle was applied to another arrangement which seems to afford the maximum of electric development from a given magnetic power; in place of the two pieces of iron and the armature used in the last experiments, the poles of the magnet were connected by a single rod of iron, bent into the form of a horseshoe, and its extremities filed perfectly flat so as to come in perfect contact with the faces of the poles; around the middle of the arch of this horseshoe, two strands of copper wire were tightly coiled one over the other. A current from one of these helices deflected the needle one hundred degrees, and when both were used the needle was deflected with such force as to make a complete circuit.

When two clouds approach each other in the summer sky, the electricity in them is manifested by the lightning which leaps from one to the other. Henry desired a similar manifestation of the electricity he could make his magnets produce, and in the next experiment he obtains this in *the electric spark.*

But the most surprising effect was produced when, instead of passing the currents through the long wires to the galvanometer, the opposite ends of the helices were held nearly in contact with each other, and the magnet suddenly excited; in this case a small but vivid spark was seen to pass between the ends of the wires, and this effect was repeated as often as the state of intensity of the magnet was changed.

The Paper closes with the discovery of the "extra current," which we have shown Henry making in 1829, distinctly inserted here, we ask the reader to notice, as a phenomenon of the same order. Five years later, in 1834, this fact, rediscovered by Faraday, formed another star in his crown.

ELECTRICAL SELF-INDUCTION IN A LONG HELICAL WIRE.

I have made several other experiments in relation to the same subject, but which more important duties will not permit me to verify in time for this Paper. I may, however, mention one fact which I have not seen noticed in any work, and which appears to me to belong to the same class of phenomena as those before described; it is this: When a small battery is moderately excited by diluted acid, and its poles, which should be terminated by cups of mercury, are connected by a copper wire not more than a foot in length, no spark is perceived when the connection is either formed or broken; but if a wire 30 or 40 feet long be used instead of the short wire, though no spark will be perceptible when the connection is made, yet when it is broken by drawing one end of the wire from its cup of mercury, a vivid spark is produced. If the action of the battery be very intense, a spark will be given by the short wire; in this case it is only necessary to wait a few moments until the action partially subsides, and until no more sparks are given from the short wire; if the long wire be now substituted a spark will again be obtained. The effect appears somewhat increased by coiling the wire into a helix; it seems also to depend in some measure on the length and thickness of the wire. I can account for these phenomena only by supposing the long wire to become charged with electricity, which, by its reaction on itself, projects a spark when the connection is broken.

ON THE LAW OF HYSTERESIS.*

BY CHAS. PROTEUS STEINMETZ.

(Continued from page 387.)

III

A third set of determinations of the hysteretic loss of energy is given in the following:—

A magnetic circuit was built up of 17 layers of a soft kind of sheet iron, each layer consisting of two pieces of 20cm. length, 2·54cm. width, and two pieces of 7·6cm. length and 2·54cm. width, of the thickness $\delta = 0686$cm.

Here evident proof of the induction of eddy currents in the iron was found. Especially perceptible was a decrease in the watts consumed by the iron, when a larger M.M.F. of high frequency was left acting upon the iron. This decrease must be attributed to the increase of the electric resistance of the iron, caused by its increasing temperature.

To eliminate this source of error as far as possible, before each set of tests an alternating current of high frequency ($n = 200$), and considerable strength was sent through the magnetising coils, and left on for ten to fifteen minutes, and then first readings with low magnetisation, then with high, and then again with low magnetisation were taken. But, nevertheless, as was to be expected, in these tests the observed values agreed less with each other than in the former readings.

The method of determination, the apparatus, &c., were the same as in the second set of tests, only that ammeter, voltmeter, and wattmeter were used at the same time. In calculating these tests, the law of the 1·6th power was assumed as true, and the loss of energy in the iron expressed by the equation,

$$H = \eta B^{1.6} + \varepsilon n B^2,$$

where

$$H_1 = \eta B^{1.6}$$

is the true hysteretic loss per cycle and cm.^{3}, which is independent of the frequency; and

$$H_2 = \varepsilon n B^2$$

is the loss of energy by eddy current, per cycle, which is proportional to the frequency n.

From this expression,

$$H = H_1 + H_2.$$

* Abstract of a Paper read before the American Institute of Electrical Engineers, New York, January 19, 1892.

Digitized by Google

coefficients η and ϵ were calculated, and the agreement or disagreement of these coefficients η and ϵ allow now to check the correctness or incorrectness of the law of the 1·6th power.

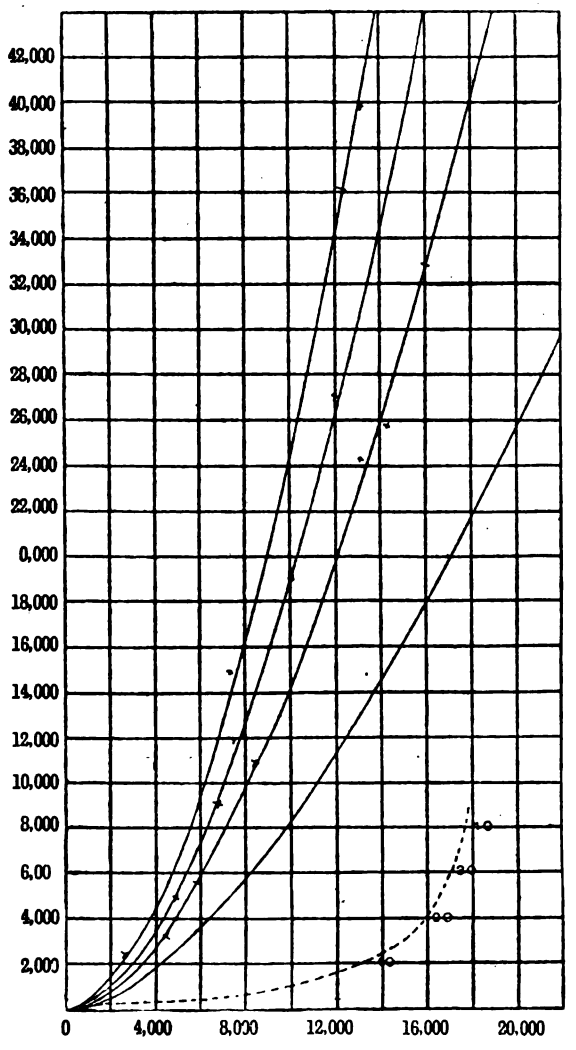


FIG. 4.

These tests gave the following results :—

Magnetic Characteristics.

F = M.M.F. in ampere turns per centimetre length of magnetic circuit.

$\mathfrak{B}$ = magnetisation in lines of magnetic force per square centimetre.

TABLE IV.

F.	$\mathfrak{B}$.	F.	$\mathfrak{B}$.	F.	$\mathfrak{B}$.
1·5	2,700	7	11,700	18	15,450
2	4,350	8	12,200	20	15,800
3	7,100	9	12,700	25	16,400
4	8,850	10	13,100	30	16,800
5	10,000	12	13,900	35	17,200
6	10,800	14	14,500	40	17,500
		16	15,000		

Hysteresis.

$\mathfrak{B}$ = magnetisation in lines of magnetic force per square centimetre.

H = loss of energy by hysteresis, in ergs per cycle per cub.-cm. ($= 10^{-7}$ joules) $= H_1 + H_2$.

$H_1 = \eta \mathfrak{B}^{1·6}$ = loss of energy by hysteresis proper, in ergs per cycle and cm.^{3} ($= 10^{-7}$ joules).

$H_2 = n \epsilon \mathfrak{B}^2$ = loss of energy by eddy-currents, in ergs per cycle and cm.^{3} ($= 10^{-7}$ joules).

Therefrom we get the results :

n = 78, 6 readings,	η = ·00331	$\epsilon = ·751 \times 10^{-6}$	... 1·9 %
140, 6 ,,	·00331	$·730 \times 10^{-6}$	... 2·2 %
207, 5 ,,	·00336	$·757 \times 10^{-6}$	... 1·6 %

The values found for η are so nearly alike that we can consider them as constant, and take their mean value

$$\eta = ·00333$$

as the coefficient of hysteresis.

Even the values found for ϵ are not much different from each other, not more than was to be expected from the unavoidable differences in the temperature of the iron, which, because of the high electric temperature-coefficient of iron, makes ϵ rather variable.

Taking the average of ϵ, we derive

$$\epsilon = ·746 \times 10^{-6}$$

and as formula of iron loss,

$$H = ·00333\, \mathfrak{B}^{1·6} + ·746 \times 10^{-6}\, n\, \mathfrak{B}^2$$

In Fig. 4 are drawn the four curves,

1. True hysteretic loss, $H = ·00333\, \mathfrak{B}^{1·6}$
2. Iron loss for n = 78 $·00334\, \mathfrak{B}^{1·6} + ·00005856\, \mathfrak{B}^2$
3. ,, ,, 140 $·0001022\, \mathfrak{B}^2$
4. ,, ,, 209 $·0001567\, \mathfrak{B}^2$

The observed values are plotted by crosses, +

IV.

Two other sets of determinations of the hysteretic loss of energy, for the frequency 170 complete periods per second, were made on two laminated horse-shoe magnets, with laminated keeper or armature.

The method of observation and of calculation was the same as in III., and the same precautions were taken.

The dimensions of the horse-shoe magnets were :

Mean length of magnetic circuit : 38cm.
,, cross-section : 70cm.^{2}
,, volume of iron : 2,660cm.^{3}
,, distance of keeper from magnet, in the first case : ·15cm.
,, distance of keeper from magnet, in the second case : ·08cm.

each magnet consisting of 300 sheets well-insulated iron, of the thickness ·0405cm.

In the first set of readings, considerable eddy-currents were found ; in the second set, only a small amount of eddies.

The magnetic susceptibility of the iron was not determined, because the reluctance of the magnetic circuit mainly consisted of that of the air gap between magnet and keeper.

The results for the first magnet were

Frequency, $n = 170$.

$$\eta = ·0045 \qquad \epsilon = 1·16 \times 10^{-6}.$$

Therefore we get the formula for the loss in the iron,

$$H = ·0045\, \mathfrak{B}^{1·6} + 1·16\, n \times 10^{-6}\, \mathfrak{B}^2.$$

In Fig. 5 are shown

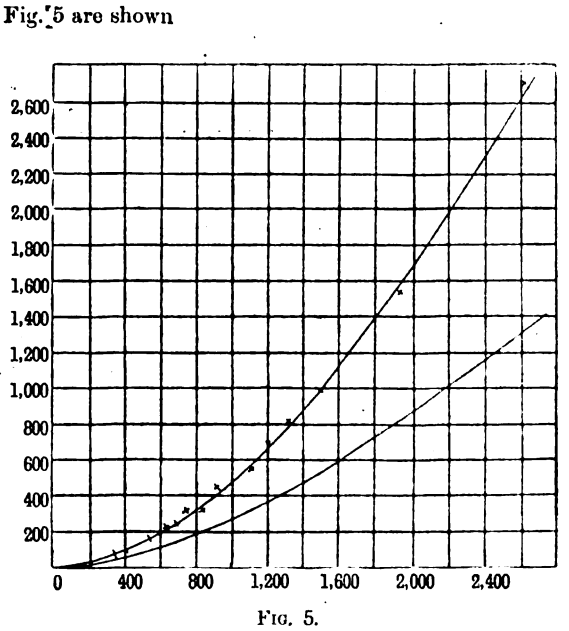

FIG. 5.

1. The curve of true hysteretic loss,

$$H_1 = ·0045\, \mathfrak{B}^{1·6}$$

Digitized by Google

2. The curve of the whole loss in the iron,

$$H = H_1 + H_2$$

with the observed values marked by crosses +

For the second magnet the results were

Frequency $n = 170$

$\eta = \cdot00421$ $\epsilon = \cdot2083 \times 10^{-6}$

Therefore we get the formula for the loss in the iron

$$H = \cdot00421\ B^{1\cdot6} + \cdot2083 \times 10^{-6}\ n\ B^2.$$

In Fig. 6 are shown,

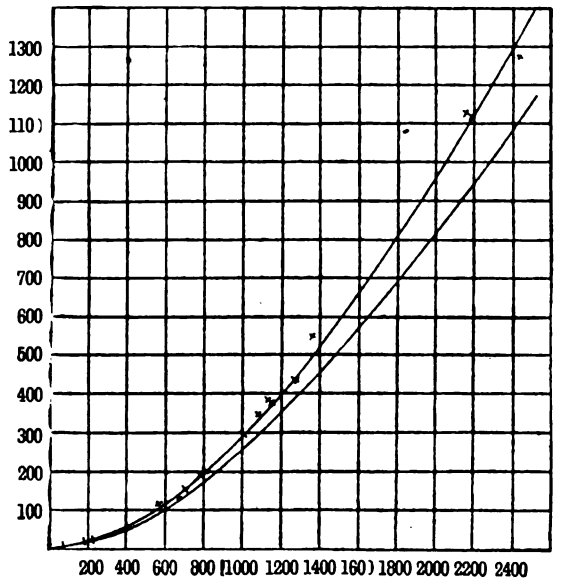

FIG. 6.

1. The curve of true hysteretic loss

$$H_1 = \cdot00421\ B^{1\cdot6}$$

2. The curve of the whole loss in the iron,

$$H = H_1 + H_2$$

with the observed values marked by crosses +

Especially interesting are these two sets of readings in so far as they cover quite a different range of magnetisation as the tests in I. to III.

In I. to III. the tests cover the range from 1,790 to 19,340 lines of magnetic force per cm.^{2}, that is from medium magnetisation up to high saturation, while the tests in IV. cover the range from 85 to 2,600 lines per cm.^{2}, that is, from medium down to very low magnetisation.

The law is found exactly the same,

$$H = \eta\ B^{1\cdot6} + \epsilon\ n\ B^2$$

and herewith proved for the full range from 85 lines per cm.^{2} up to 19,340 lines, a ratio from $1 \div 230$.

This seems not to agree with Ewing's theory of the molecular magnets. According to this theory, for very small magnetisation the hysteresis should be expected to disappear, or almost disappear, and the cycle be reversible. Then for medium magnetisation, where the chains of molecular magnets break up and rearrange, hysteresis should increase very rapidly, and slowly again for saturation. Nothing of this is the case, but hysteresis seems to follow the same law over the whole range of magnetisation, and is certainly not zero for even such a low magnetisation as 85 lines per cm.^{2}

[ERRATA.—The ordinates of Fig. 2 (p. 386) of this article were numbered incorrectly last week, the figures being, by a printer's error, all placed a line too low. The ordinates of Fig. 3 also should read 0, 2000, 4000, &c., and not 0, 4000, 6000, &c.]

(To be continued.)

Armature Resistance.—"Only for the resistance of the armature and field-winding," remarked an engineer, "we could get any amount of current out of a dynamo." This is the truth, but not "the whole truth;" for if the armature and field-winding possessed no resistance, the dynamo would be burned out the very first time it was started up.

DEVELOPMENTS OF ELECTRICAL DISTRIBUTION.*

BY PROF. GEORGE FORBES, F.R.S.

Two distinct problems arose in connection with the electrical utilisation of water-power. It might be used for lighting and other purposes in country houses, &c., or it might be necessary to transmit a large amount of energy to a great distance. It was worth while to introduce a word or two of caution in connection with the use of water-power for house lighting. It was generally a matter of extreme difficulty to find out what was the exact amount of power which could be obtained from a source of supply. In this country there was, as a rule, a superabundant flow of water in winter, and a diminished supply in summer, which was convenient. But it often became extremely doubtful whether the summer supply would be sufficient for the summer demand. It was a most injudicious thing to set up hydraulic plant without taking measurements during the summer. On the other hand, frost in winter often behaved in an unexpected manner, and froze streams which had never been known to freeze before. Even in such cases, however, a saving would be effected if turbines were used in conjunction with a steam plant, owing to the economy of water power. When the source of power was not exactly on the spot another point had to be borne in mind, namely, the proper size of cable to be employed. In many cases with the source of power half a mile away people had acted on the assumption that it would not greatly affect the size of the conductor.

For transmission purposes the alternate-current system was in most cases the best; nevertheless, it was quite easy to imagine circumstances which would make continuous currents suitable. At the present time two types of alternating machines were the best for the transmission of power—the synchronising machine and "rotary phase" machine. It might be worth while to remark that while light alternators would not work well as motors when used with a single pair of conductors, we could use them in the manner described in the previous lecture†, where heavy alternators would be unsuitable.

It was desirable that attention should be drawn to what was being done in Switzerland in connection with the utilisation of water-power. Switzerland was quite in the front rank in this respect. Two large hydraulic systems were in operation at Geneva and Zürich, and being very similar, he would confine his remarks to the former town. At Geneva the Rhone only gave a fall of from 6ft. to 12ft., the higher figure obtaining in the summer when the snows melted. Owing to the small fall, large turbines were requisite. Some twenty were now at work, capable of supplying 6,000 H.P. These large turbines pumped water to a high-level reservoir, whence it was distributed at high pressure to small hydraulic motors all over the town.

The electric lighting of the town was carried on by a separate company. Now the central station was on an island in the Rhone, and close to the turbine station. Nevertheless, the terms upon which hydraulic power was supplied were so reasonable that the company found it more economical to rent what hydraulic power it wanted from the town than to lay down its own hydraulic plant. We therefore had the curious and somewhat anomalous spectacle of a central station, within a hundred yards of the turbine house, driven by water which was first pumped by these turbines to a distant high-level reservoir, and then brought back again.

When we considered the noise, vibration, dirt, and lack of economy of a steam-engine and boiler plant worked under central-station conditions, cases might really arise, even in this country, where saving might be effected by laying down a comparatively small pumping plant, pumping water to a height, and using the water to drive turbo-dynamos. For instance, at Edinburgh it was possible to obtain water and pump it up to the top of Arthur's Seat, 800ft. above the sea level. Loch Dunsappie was already of sufficient cubic capacity to contain a quantity of water capable of supplying 1,000 H.P. for two hours. But a dam could be built across a gully nearer the summit, giving a far greater height. It would cost but little, and in no way mar the beauty of the hill. If we took a station which supplied a maximum of 1,000 H.P.; the average demand would not be more than 150 H.P. A 150 H.P. pumping plant might, therefore, be laid down and worked continuously day and night pumping water to the summit of Arthur's Seat, the head of water so obtained being used to drive turbo-dynamos. Using Loch Dunsappie, and putting the cost of engines and boilers against that of turbines and piping, a great saving in capital outlay would be effected, and a still greater annual saving would be possible. Including losses in pipes a H.P.H. would be available at the turbines for 3lb. of coal, whereas 10lb. to 15lb. was more like the figure reached by central stations. He (Prof. Forbes) had worked this out in the case of Edinburgh for his own satisfaction. The matter had been laid before the authorities, and it was to be

* Abstract of Cantor Lecture II., 4, delivered before the Society of Arts, February 15, 1892.

† *The Electrician*, February 12th. p. 388.

Digitized by Google

hoped some such scheme would be adopted. The capital expenditure would be but little more than one-half of that necessary for a steam plant, and the saving in attendance and fuel would also be about 50 per cent.

The increasing use of "destructors" as a means of getting rid of town refuse afforded another source of power. Few engineers had gone into the question of "destructors." His own attention had been called to the matter some years ago, when he was called in to advise Paddington. Since then he had gone into the question carefully, and had inspected a large number of the "destructors" in use. Paddington had a population of 112,000, and 21,000 tons of refuse were annually destroyed in that parish. Assuming this proportion to hold generally and assuming (as was usually done) that each inhabitant required one lamp, then by a wise provision of nature it happened that the average refuse of a town sufficed to generate the average amount of light required by its inhabitants. At Paddington, after deducting all profit, it cost £1,000 per annum to get rid of the refuse. The first "destructors" had not been very great successes, owing to insufficient draught. The type most widely used hitherto was known as Fryer's patent, and was made by Manlove, Alliott and Co. The city which led the way in the scientific use of "destructors" was Leeds, where the destruction of refuse cost 1s. 3d. per ton (interest included).

Prof. Forbes concluded by reiterating his remarks *re* transformer sub-stations and low frequencies.

ART FITTINGS AT THE CRYSTAL PALACE.

We have frequently quoted from the columns of our contemporary, the *Journal of Gas Lighting*, in which very fair comments upon electrical work are often to be found. Mutual admiration is as bad for electrical engineers as for other classes of the community; and a little criticism from their rivals will do them no harm. If the language of the following extract from an article on the Crystal Palace Exhibition is rather strong, we hope to soothe any feelings which may be injured by noticing some really good work on a future occasion.

We all know what the electric arc can do; and the lightness and handiness of the incandescent bulb, with its freedom from flame, would seem to offer a wide range of novel application to the ingenious technician. Our investigation resulted in disappointment. There is a terrible want of originality, and a deplorable absence of taste, observable in most of the exhibits of lighting and lamp-fittings. Electrical science has its Edison, its Swan, and its Brush; but the brilliant stroke of genius that gave the world "French measurement" in electric lighting, exhausted the invention of electricians in this field. The curse of the commonplace lies heavy on the makers of electric light fittings; and it is an object-lesson in the character of the culture of the age to compare the beauty of fitness, as displayed in a modern steam-engine, with the poverty, emptiness, and downright vulgarity of the great bulk of electric light fittings. It is hardly credible, but it is nevertheless too true, that, in the utter debasement of their "art," the fitting makers have taken infinite pains to make imitations of wax-candles-flames and all—out of incandescent lamps! These wretched impositions are to be seen at the Palace by hundreds; and they inspire the thoughtful observer with inexpressible disgust. When the poor ignorant gas-fitters of the early Victorian period put up their glassy imitation candles, surmounted with batswing flames, they knew no better; and the artist in decoration was not then evolved. These fittings would now be regarded as curiosities, wherever found; and we take a little credit to ourselves for having pointed out the absurdity of such imitations many years ago. What might have been pardonable in the uninstructed gas-fitters of the middle of the century, moreover, is abominable in their "advanced" rivals of to-day. These sinners against artistic veracity and consistency are, however, shameless in their turpitude. Take one of the most "bumptious" of them all—the firm of Rashleigh Phipps and Dawson, who have spread themselves very much over the official catalogue. This firm tells purchasers of this publication that their "showcase is after the model of a Mosque at Cairo, and has been specially designed and manufactured by the firm. The lily is introduced in the screen work, after the manner of the Ancient Assyrians, who held it as an object of veneration. The dome is covered in with glass and amber cloth, and is in the form of the breast—a suggestion that Peace nourishes the Arts and Sciences." There is much more of the same style, intended to impress readers with a deep sense of the high-toned work shown in this wonderful stall. Yet here also we find imitation candles "after the manner of the ancient"—gas-fitters! But this firm are not alone. It is the same with Messrs. Benham and Froud, Messrs. Allen and Mannooch, and many others. Sometimes the sham candle-flame is a cylindrical bulb of clear glass with elongated incandescent fibre; sometimes it is in the form of a spiral, frosted or plain, with irregular section, to still more closely copy a flickering candle flame. But, in one or another of these shapes, the scientific decorators of the Palace Exhibition propose this patent lie as the proper thing for their patrons to keep under their eyes daily and nightly! Imagine sitting at a dinner-table so lighted, as may be seen in Messrs. Allen and Mannooch's room in the South Gallery! One would expect to be served with logwood-port, fuchsine-claret, and cider-champagne at such a table; and who could confidently partake of jugged hare, *vol-au-vent*, or other mysterious dish under such a prevaricating light? One firm of exhibitors—Messrs. Frank Giles and Co.—actually go so far as to place imitation wax candles of huge proportions, such as are never seen outside Catholic churches, in one of their specimen rooms, and top these off with ordinary incandescent bulbs. It is difficult to tell the tale patiently. The example just named is perhaps the worst in the list; but an imitation candle, whether large or small, is an outrage hard to be borne. The sight of it is enough to make anybody rush home and light up the real article, with the feeling of relief that here, at least, there is no deception. In order that the subject of these so-called "flame-lamps"—this is, we are informed, their trade name—may be understood, it may be stated that they are a product of the last year or two. They can, of course, be employed quite unobjectionably as "fairy lamps" for decorative purposes. They take 33 volts, and are connected in series of three when the group becomes equivalent to one 100-volt lamp. It requires, however, more taste in lighting than most decorators seem able to command, to employ these or any other description of incandescent lamps in such a manner as to be truly ornamental as well as useful.

THEATRE LIGHTING.—LONDON COUNTY COUNCIL REGULATIONS.

The following Rules and Regulations with regard to the electric light in theatres and other places of entertainment have been adopted by the London County Council:—

Where the electric light is permitted in such premises, it shall be on condition that a competent electrical engineer do certify in writing to the satisfaction of the Council once in six months that the system is in proper working order.

1. All such premises when lighted by electric light shall have at least three separate and distinct circuits (*a*) for the stage, (*b*) and (*c*) for the auditorium, corridors, and exits. The circuits referred to in (*b*) and (*c*) shall be so arranged that half the lights in each division of the auditorium and half those in each corridor and exit shall be on (*b*), and the other half on (*c*) circuit. When the current is supplied by a public lighting company, these circuits shall be taken separately from the street mains.

Under all circumstances complete metallic circuits must be employed. Gas and water pipes shall never form part of any circuit.

The number of lamps shall be so subdivided that no sub-circuit shall carry more than 65 amperes, and each sub-circuit shall start from a distributing board.

2. All conductors used within buildings shall be of copper, having a conductivity equal to not less than 98 per cent. of that of pure copper, and, shall be so proportioned to the work they have to do that, if double the normal current be transmitted, their temperature shall not rise to above 150° Fahr.

The conductors shall be insulated with pure and vulcanised India-rubber. The insulation resistance shall not be less than 300 megohms per statute mile, at 60° Fahr., after one minute's electrification, when tested with at least 400 volts, and after 48 hours immersion in water. The insulated conductors shall be protected on the outside by stout tape or braiding impregnated with preservative compound.

If it is desired to use any other means of insulation than that above specified, special permission shall be obtained from the Council, and no material shall be used which is not waterproof, or which will soften at a temperature below 170° Fahr.

In all cases conductors conveying currents of high E.M.F. inside buildings, shall be specially and exceptionally insulated, and cased in, and the casing made fireproof. The positive and negative terminals connected to such conductors shall not be nearer to each other than 12 inches, and shall be efficiently protected from risk of contact.

Flexible conductors in connection with movable lights shall be insulated with vulcanised India-rubber, and protected on the outside by a stout braiding; should any of these flexible conductors be damaged, it shall be at once replaced. No circuit of this nature shall carry more than 10 amperes, and each circuit shall be protected by a double pole fuse.

3. All conductors shall be efficiently protected from mechanical injury.

When conductors pass through walls, fireproof floors, or ceilings, they shall be protected by iron pipes or by glazed stoneware or porcelain tubes, and precautions shall be taken to prevent the possibility of fire or water passing along the course of the conductors.

Digitized by Google

In special cases, or where necessary for protection from the depredations of rats, mice, or other vermin, armoured cables may be used. These need receive no further mechanical protection.

Lead-covered cables shall not be used unless protected by external armour of iron or steel.

Metal fastenings for fixing conductors shall be avoided; but when unavoidable some additional covering shall be used to protect the conductor, unless armoured, from mechanical injury at the points of support.

If casing be used it shall be of hard wood, and each conductor shall be laid in a separate groove; the cover shall be secured with screws. Casings shall, as far as possible, be placed in sight, and the conductors shall always be accessible.

Joints in conductors shall be avoided, but when unavoidable, they shall be electrically and mechanically perfect. Soldering fluids shall not be used in making such joints.

4. All external conductors shall be specially insulated and laid in iron pipes properly jointed, and of ample size. Such iron pipes shall be protected where necessary, and securely fixed and supported when not underground.

5. All exposed metal work, such as fittings, switch and fuse covers, &c., shall be efficiently insulated from the circuits.

All switches, cut-outs, ceiling roses, wall and floor sockets, and lamp-holders shall have uninflammable bases. All switches shall be of ample size to carry the currents for which they are intended without heating, and shall be so constructed that it will be impossible for them to remain in any position intermediate between the "on" and the "off" positions, or to permit of a permanent arc. All circuits shall be efficiently protected by cut-outs, placed in positions easily accessible to the staff, but inaccessible to the public. The main cut-outs shall be of such pattern and be fixed in such a position as to admit of quick replacement. All circuits carrying a current of 20 amperes or more shall be provided with a cut out on each conductor, and the two cut-outs shall not come in the same compartment. All cut-outs shall be so constructed that fused metal in falling cannot cause a short circuit or an ignition. All cut-outs shall be so marked as to show what circuit or lamps they control. All wall or floor sockets shall be provided with fuses in their fixed portions. The sockets for the stage shall be of hard wood with metal guards, care being taken to avoid risk of ignition, and they shall be of specially substantial construction.

6. Resistances, for regulating the power of the lights, shall be mounted on incombustible bases, and shall be so protected, and placed at such a distance from any combustible material, that no part of the resistance, if broken, can fall on such material.

Principal resistances sha'l be placed in a fire-proof room reserved for the purpose.

7. Arc lamps shall not be used inside buildings without special permission from the Council.

When they are used, special precautions shall be taken to guard against danger from falling glass or incandescent particles of carbon. All parts of the lamps, lanterns, and fittings which are liable to be handled (except by the persons employed to trim them) shall be insulated.

8. Where there is a stage, special care shall be taken that all works in connection with the lighting of the stage are carried out in as substantial a manner as possible.

No metal work in connection with the circuits shall be exposed, or so fixed or constructed as to be liable to cause a short circuit.

Lamps on battens, footlights, &c., shall be protected by stiff wire guards, so arranged that no scenery or other inflammable material can come in contact with the lamps.

No readily combustible material shall be used in connection with any lamps on the stage in such a manner that it might come in contact with the lamps.

No soft or readily inflammable wood shall be used in connection with the lamps on the stage, and all wood shall be protected by uninflammable material from the possibility of ignition by an arc between any two parts of the two conductors, or by heated particles from any conductor or part of a conductor which may connect together the two main conductors.

Where a number of lights, as in the footlights, battens, &c., are supplied under control of one switch, and protected by one single or double pole cut-out, as the case may be, the conductors shall be maintained throughout of such a section that they will be effectually protected by the cut-outs against heating.

The leads to the battens shall be specially guarded, particularly at the points where they join on to the battens, and a sufficient length shall be allowed to prevent the leads receiving any injury through any movement of the battens.

The battens shall be suspended by at least three wire ropes attached to insulators on the battens.

On no account shall the same battens be adapted for both gas and electric light.

9. A switchboard, containing all the necessary switches, cut-outs, and other fittings for the control and regulation of the stage lighting, shall be fixed in some convenient position overlooking the stage. This board shall be inaccessible to all but the persons employed at such premises to work it.

10. Boilers, steam engines, gas engines, and dynamos, when used for the supply of electricity to such premises, shall be placed in such positions as shall be sanctioned by the Council.

Gas engines shall be placed in rooms so adequately and continuously ventilated that no explosive mixture of gas can accumulate by any leakage through the engine in the event of any of the gas cocks being left turned on. A hood, connected with a pipe carried into the external air, shall be fixed over the ignition tube when this is used.

11. Primary or secondary batteries shall be placed in rooms so adequately ventilated that no fan shall be necessary. The batteries shall be well insulated.

12. Transformers used to transform either direct or alternating currents, together with the switches and cut-outs connected therewith, shall be placed in a fire and moisture proof structure. Where the primary current is of high potential, such structure should be preferably outside the building. No part of such apparatus shall be accessible except to the person in charge of its maintenance.

No transformer which, under normal conditions of load, heats above 130° Fahr. shall be used.

Transformer circuits shall be so arranged that under no circumstances shall a contact between the primary and the secondary coils lead an E.M.F. of high pressure into the building. The term high pressure means in all cases pressure above 200 volts.

13. The insulation resistance of a system of distribution shall be such that the greatest leakage from any conductor to earth, when all branches are switched on, the lamps and motors being removed, shall not exceed one fifteen-thousandth part of the total current intended for the supply of the said lamps and motors, the test being made at the usual working electromotive force. Provided that this rule shall not be held to justify a lower insulation resistance than 5,000 ohms, nor to require one higher than 5 megohms.

14. The generating plant and switching gear shall be in the hands of thoroughly competent manipulators, and the engine-room (if any) shall be inaccessible to the general public, and shall, where possible, have an independent entrance.

15. A plan of the wiring shall be always kept in a prominent position n the office of the manager of such premises.

ELECTRIC PERCUSSION DRILLS.

Several installations of electric percussion drills, says the *Engineering and Mining Journal* of New York, have been made in mines in various parts of the country during the past year; and it must be confessed that the results obtained from these machines in practice have not borne out the expectations that were based upon the experiments made in the manufacturers' workshops. It has been demonstrated by actual work in the mines that the electric drills are of faulty construction; and although this defect can doubtless be easily corrected, it would appear to be a more serious matter to overcome the chief trouble, viz., the heating of the solenoids and piston. All of the electrical percussion drills which have been invented so far are based upon the same principle, consisting of two or three solenoids, within which works an iron core or piston (*The Electrician*, November 6, 1891, p. 9). The reciprocating motion of the latter is attained by sending an electric current first through one solenoid and then through the other, the iron core being alternately attracted, first in one direction and then the other. The other parts of the drill, the piston-rod, the rifle-bar, the feed-screws, the tripod, &c., are in general form similar to those used in the ordinary types of steam and air drills. There is an essential difference, however, in the fact that the piston-rod and rifle-bar have to be constructed of non-magnetic material in order not to interfere with the balance of the piston within the solenoids. The heating of the solenoids seems to be due to the rapid reversing of the electric current through their coils. This not only means such loss of power as to make the drills uneconomical, electrical energy being converted into heat which should be converted into mechanical work, but the heating is often so intense as to make the drill objectionable in a small mine heading. Several months ago an important installation of these drills was made in the Ute and Ulay Mines at Lake City, Colo., from which much was expected. The plant was completed and ready to run about September 10th, and the experiments continued through September and October. Many mechanical difficulties were encountered, some of which were overcome, but the great trouble was the heating of the machine. After much work upon this problem, the electricians decided to give it up for the present. A like experience was had at the Last Chance Mine, at Wardner, Idaho. Although the electric percussion drills have not realised expectations, it is not to be inferred that they will not eventually become successful. Indeed, the haste of the manufacturers in putting them in the mines before they were fully tested, is probably accountable for this temporary set-back. The inventors are now endeavouring to overcome the defects that have been shown, and such bright minds as Edison, Thomson, and Van Depoele cannot long be denied.

AMERICAN NOTES.

(FROM OUR OWN CORRESPONDENT.)

NEW YORK, *February* 5, 1892.

Rumoured Amalgamation of the Thomson-Houston and Edison Companies.—The principal rumour of interest in electrical circles just now is the alleged formation of a combination between the Thomson-Houston and Edison Companies. This has been reported at various times in the past, but never with so much substantial foundation as now. It is known that consultations between the officials of these companies have been several times held recently, and to-day the understanding is that a definite result has been reached. The details, of course, are totally unknown, but it is altogether probable that the Thomson-Houston Company has the butt of the whip. One of the rumours which seems to be generally believed is that a gigantic corporation will be formed, in which both companies will be merged, perhaps without entirely giving up their individual organisation. Mr. C. A. Coffin, president of the Thomson-Houston Company, is supposed to be at the head of the combination. It is suggested further that the incandescent lighting business for both isolated plants and central stations, the manufacture of lamps, fittings, cables, and the like, together with the exclusive manufacture of generators, will be given to the Edison organisation, the Thomson-Houston running the transmission of power, railway, and mining business. This, of course, is pure hypothesis. There is some foundation for the rumours, although nothing can be definitely confirmed until after the Edison Company's next meeting, and possibly not until the Thomson-Houston meeting in March. The stock of both companies has risen very rapidly, Thomson-Houston, par value of 25, being quoted last night at 59, and Edison, par value 100, at 103. That Mr. Henry Villard will go is generally admitted, and it is understood that Drexel, Morgan & Co. now have the control of the Edison organization. The result of such a combination of the two organizations would be a tremendously powerful corporation that would acquire and retain a very large proportion of the electrical work of the country. It would also prevent the ruinous cutting of prices that has been indulged in during the last year. There is a strong feeling, too, in the trade that the supply business is likely to be taken up by the large companies, making it hard for the small dealers to live. Meanwhile, with all this, there is a promise of a very large amount of construction work the coming season, enough to keep all the companies busy.

A Novel High-Speed Electric Railway.—A Company has recently been organised for the purpose of running a high-speed electric railway between Chicago and St. Louis, a distance of 250 miles. Their plans look formidable on paper, but there does not appear to be any general confidence that anything serious will result. The proposition to operate a 250-mile road from one station is enough to cast considerable doubt on the genuineness of the scheme even if nothing more were said, and the plan of buying up the land along the track and building a grand residence boulevard between the cities, seems almost equally absurd. We are doubtless to have high-speed electric roads in the near future, but hardly of the character suggested.

The Proposed Adoption of Electricity on the Illinois Central Railway.—The Illinois Central, which has proposed the extensive use of electricity in its suburban traffic, appears now to have decided to do nothing until after the World's Fair, feeling that the time is not quite ripe for such a change, especially on the eve of an unprecedented heavy traffic. The Illinois Central is said to have the largest suburban traffic of any single road in the world, and is therefore cautious about inaugurating a change.

CORRESPONDENCE.

THE EXCITATION OF VACUUM TUBES WITHOUT ELECTRODES.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I think that a reprint of the following letter may, even now, be not without interest to some of your readers. It explains the electrostatic excitation of vacuum tubes without electrodes. The letter was originally printed in *Nature*, Jan. 6, 1881:

TO THE EDITOR OF NATURE.

SIR: At a meeting of the Philosophical Society of Glasgow, on December 22, I gave a very brief preliminary account of some experiments that I have been making, along with Sir William Thomson, with vacuum tubes. We have sealed up English and German glass tubes with very high vacuums, but without any electrodes; and have obtained very remarkable luminous effects both with the Ruhmkorf coil, and also working by means of electrostatic induction. Using an ordinary frictional electric machine, and applying one end of a long vacuum tube to the prime conductor, while the other end of the tube is held in the hand, the tube becomes charged as a double Leyden jar in the following way:—One end of the tube next to the prime conductor—outside positive, inside negative; the other end—inside positive, outside negative. This can be shown by the gold-leaf electroscope. The charges seem to be very high and the glass is very frequently perforated. Indeed, it is difficult to work with the electric machine in tolerably good order without perforating the glass. While this double Leyden jar is slowly discharged by removing, part by part the charges from the outside of the tube, beautiful luminous effects were observed, very different from those seen in the ordinary vacuum tubes. We have also obtained curious effects by heating the middle region of the tube so highly that it becomes a semi-conductor. J. T. BOTTOMLEY.

Physical Laboratory, University, Glasgow, Dec. 29, 1880.

The electrostatic mode of excitation ought, obviously, to be clearly distinguished from the method used by Prof. J. J. Thomson, in the experiments which he showed so beautifully to the Physical Society at Cambridge last June. The illumination of the tubes when the Ruhmkorf coil was employed was, probably, not wholly electrostatic. The tube was simply held in the hand above the line where the sparks from the coil were passing, and in these circumstances became illuminated.—Yours, &c., J. T. BOTTOMLEY.

Feb. 13, 1892.

THE SPECIFIC RESISTANCE OF COPPER.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: I have lately had to deal with two samples of copper strip obtained from the same firm, and have found that the specific resistance of one specimen is 2·9 times as great as that of the other. I should be glad to know whether there is often so great a difference among samples of commercial copper. The copper was obtained from a firm of the very highest standing.—Yours, &c., G. F. C. SEARLE.

Cavendish Laboratory, Cambridge, Feb. 15, 1892.

TESLA'S EXPERIMENTS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: While impressions of Mr. Tesla's experiments are still fresh in the minds of those present at the Royal Institution, I ask permission to call attention to one or two points that may refer to the nature of electricity and magnetism.

An insulated conductor was suspended from above the head of the lecturer to the front of the gallery and back again, in two lines slightly converging towards the gallery. When this conductor was placed in the electric circuit and the room darkened, its whole length glowed with a beautiful violet haze, appearing equally vivid at all parts of the conductor. The haze surrounding the conductor in that space we find imbued with magnetism, when current is passing. Mr. Tesla also connected up two bare wires of circular form, and different diameters, placed concentrically and in the same plane. These, likewise, showed the same violet haze, but directed (like streamers of the aurora borealis) towards each other. In this last experiment the haze seemed less vivid than in the former one, and I should like to know if this is the opinion of others who were present. Of course, the frequency or potential may have been changed, or the relative position of the conductors may affect the haze; but, as we found that a di-electric placed between two sparking terminals facilitated the discharge, it may be that the haze was increased by the use of insulation. If this be so, it is important to know under what change of conditions insulation would cease to facilitate

Digitized by Google

discharge or vary the magnetic haze, as it might then be used as a test of the quality of insulating material.

My next point is that the violet or magnetic haze would imprint an image on a sensitised photographic plate probably without the aid of a lens or other light than its own. We know how sensitive such plates are to blue and violet rays of the spectrum; and we know that stars, never seen by man, appear on plates after a lengthened exposure. By calling in, therefore, the aid of another branch of science, we may yet be able to see the exact image of varying electrical or magnetic conditions permanently recorded and comparable at sight; and we may also hope to acquire further knowledge of these subtle forms of energy.—Yours, &c.,

London, W.C., Feb. 15, 1892. J. SINCLAIR FAIRFAX.

LEGAL INTELLIGENCE.

Crompton and Co. v. Lane-Fox.

In the Queen's Bench Division of the High Court of Justice, on Monday, the case of Crompton and Co. *v.* Lane-Fox came before Mr. Justice Day, sitting without a jury. This was an action brought by the plaintiffs, electrical engineers, carrying on business at Chelmsford and London, against Mr. Lane-Fox, also an electrical engineer, to recover £150 alleged to be due under a contract. The defendant denied liability.

Mr. Bankes appeared for the plaintiffs, while Mr. Forbes Lankester represented the defendant.

Mr. BANKES, in opening the case for the plaintiffs, said his clients were well-known electrical engineers; and Mr. R. E. Crompton, the head of the firm, was a friend of the defendant, who was also engaged in electrical engineering. The plaintiffs were in the habit of taking pupils, and their premium was £300 for three years' tuition, £150 being paid down when the pupil commenced his articles, and the balance at the expiration of a certain period. These terms were well known to the defendant. About April, 1886, the defendant had a brother who was about leaving college, and he was anxious that his brother should become a pupil of the plaintiffs. On April 4th the defendant wrote to the plaintiffs, asking them if they could take any more pupils, as his youngest brother, who was just leaving Cambridge, wished to become an electrical engineer. Subsequently the defendant and his brother went down to Chelmsford, and saw Mr. R. E. Crompton, and it was arranged that the brother should come for a month on probation. At the end of the month the plaintiffs felt that the brother was not likely to prove a success, and they communicated their opinion to the defendant Another interview took place, with the result that the young man was taken on for a second month's probation. At the end of the second month the plaintiffs felt that the brother had improved, and they arranged to accept him as a pupil on the usual terms. Mr. Crompton was told by the defendant that his father, General Pitt Rivers, was abroad, and that the premium could not be paid until the father returned. Some time after General Pitt Rivers returned to this country, and the plaintiffs, at the suggestion of the defendant, wrote to the father asking for the payment of the premium. The father replied that he had given no authority for the lad to be placed with the plaintiffs, and that he refused to have anything to do with the arrangement. On being informed of his father's reply the defendant agreed to pay the half premium, £150, in about three weeks. The brother remained with the plaintiffs until the following June, when he left.

Mr. R. E. Crompton, of the firm of Messrs. Crompton & Co., stated that it had been the practice of his firm to take pupils on terms which were known to the defendant. On 4th of April, 1886, he received a letter from the defendant asking him if he could take his brother as a pupil. Subsequently the defendant and his brother came down to Chelmsford, and it was then arranged that the brother should come on a month's probation. At the end of the month he wrote to the defendant, telling him that his brother was not getting on well, and that he did not think he would ever make an engineer. The defendant asked him to try his brother a little longer, and he (witness) agreed that he should remain another month on probation. By the end of the second month defendant's brother had made considerable progress; and witness had a conversation with the defendant, with the result that it was agreed the brother should become a pupil for three years. The defendant said his father, General Pitt Rivers, was abroad, and that the premium, &c., would be arranged as soon as he returned. After waiting some time, witness asked the brother why he had not heard about the premium; and the brother recommended him to write to his father. Witness after having communicated with the defendant, wrote to the father, who replied that it was the first time he had ever heard of the matter. He (witness) thereupon saw the defendant and told him the purport of his father's reply. The defendant said he would have to make some arrangement himself. Subsequently, on the 19th of January, he received a letter from the defendant promising to pay half of the premium. The brother remained with the firm until the following June, when he left of his own accord. He should not have allowed the brother to remain at the works if the defendant had not written the letter of the 19th of January.

The further hearing of the case was adjourned.

On Tuesday morning when the plaintiff was about to be further cross-examined, a consultation took place between the learned counsel and their respective clients, with the result that Mr. Bankes said it had been arranged that there should be judgment for the plaintiffs for £150 with costs. Judgment in accordance with the terms arranged.

TRADE NOTES AND NOTICES.

[*Notices for insertion under the above heading must reach the Office not later than first post Thursday morning.*]

"THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, 1892.

The tenth annual edition of the above well-known annual is now ready, price 7s. 6d.; post free, in the United Kingdom, 8s. 3d.; abroad (with the exception of a few countries), post free, 8s. 10d.

The edition consists of between 900 and 1,000 pages, and special care has been taken to make the Directorial division of the book, which has been considerably extended, thoroughly accurate and reliable.

To the Handbook division has been added several features which will be found of service to the Electrical and Allied Trades. The Digest of the Law of Electric Lighting has been thoroughly revised and brought up to date, and the most recent Board of Trade Regulations are also included. The various tables and tabulated statements relating to Central Stations, Electric Railways and Tramways, &c., have been made complete; the tables giving useful data relating to dynamos, alternators, motors, transformers, batteries, &c., have been remodelled and amplified; and a new feature is the tabulation of valuable information respecting Electrical Limited Liability Concerns.

An important feature is the space devoted to the officials of Foreign and Colonial Governments who have the superintendence of contracts and the giving of orders for electrical plant and apparatus; and as this has been kindly supplied by the various Government departments, it can be relied upon, as can also the particulars given respecting the Home Government departments.

The profession will find "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK a trustworthy work of reference, and purchasers of plant and apparatus may confidently turn to its pages for the names of all the principal firms supplying their requirements. Nearly every firm of any standing in the Electrical and Allied Trades is represented in its advertisement pages.

A digest of the contents of the book will be sent on application.

TENDERS INVITED.—The Secretary of the Earl's Court Exhibition Syndicate (Limited), West Brompton, invites tenders for lighting the Exhibition buildings and grounds at Earl's Court during the coming season, from the beginning of May to October, 1892. Particulars can be obtained by writing to the Secretary, at West Brompton, London, W.

——— We are asked to state that Mr. W. B. Hutchinson has now finished the specification for the electric lighting of Heckmondwike, Yorkshire, and that tenders are invited. Plans may be seen at the Surveyor's office.

——— The Spanish Department of Posts and Telegraphs invites tenders for the supply of 25,000 telegraph insulators, 3,000 telephone insulators, and 60 tons of 4mm. iron wire. Tenders are to reach the offices of the Department, Calle de Carretas 10, Madrid, by 2 p.m. on March 10th.

TENDERS ACCEPTED.—Galloways (Limited), Manchester, have received the order for the six boilers and four large engines for the Manchester Corporation electric light installation. The boilers will be 30ft. long by 8ft. diameter, of ⅝in. steel plates for 125lb. pressure, and will be fitted with mechanical stokers as well as double sets of steam and feed arrangements. The engines will be vertical, 17in. and 34in. cylinders, 3ft. stroke, each to give off 360 brake H.P. (or 1,440 in the aggregate), with a piston-speed of 500ft. per minute, and will be provided with special arrangement of condenser. All have to be at work by the end of July. Dr. J. Hopkinson, of Victoria-street, Westminster, is the engineer.

CITY OF LONDON ELECTRIC LIGHTING COMPANY (LIMITED).—This Company has recently issued its general conditions for wiring houses for the electric light, for use by the Company's customers. The first clause sets out that the work of wiring is generally to be carried out in accordance with the rules of the Institution of Electrical Engineers and of the Company in whose office the building is insured. No conductor of a less total area than No. 18 S.W.G. is to be used, except in the case of flexible cords, which may be equal in section to No. 20 S.W.G.; all copper to be tinned if the insulation is vulcanised. The house mains from the consumers' terminals will be taken (with the meter placed in one or two of the leads) by means of two or three conductors to distribution boards, and will thence be divided into such circuits that the current in any one will not exceed 12 amperes at times of full load. Throughout the system, one main or wire will be coloured red and the other black; all single-pole cut-outs and switches will be placed in the conductor coloured black. Installations, when tested by the Company at the full working pressure, will not have a lower insulation resistance than at the rate of 75 megohms per lamp, with all fittings and apparatus connected; and any installation failing to comply with this rule will not be supplied with current by the Company. With

Digitized by Google

the above exceptions, the rules agree generally with those of the other Metropolitan Supply Companies, full details of which will be found in the new issue of "THE ELECTRICIAN" ELECTRICAL TRADES' DIRECTORY AND HANDBOOK, pp. 133-138.

CLECKHEATON.—The new Town Hall at Cleckheaton, which was opened last week, is lighted throughout by electricity. A 14 H.P. Otto gas engine drives a compound-wound Castle dynamo, manufactured by Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne. In the large hall there are 10 "Sunbeam" lamps of 200 c.p., each suspended from the ceiling, which can be lowered at will for cleaning or renewals, whilst under the gallery are 12 glow lamps of 16 c.p. The platform is lighted by eight glow lamps, fixed to the walls on handsome brackets, and also by 12 footlights of the same capacity, arranged on a fitting specially designed for the installation. A lamp of 50 c.p. is fixed in the porch, and four similar lights are placed in the crush rooms. The offices, workshops, stores, &c, are efficiently lighted, the number of lamps being 10 of 200 c.p., 135 of 16 c.p., and half-a-dozen of 50 c.p.

LAMBTON CASTLE.—A new electric lighting plant has recently been completed for the Earl of Durham, at Lambton Castle. The two engines are the latest type of Parsons' steam turbine, running at 4,000 to 5,000 revolutions, direct coupled to the dynamos, which are shunt-wound. Each set of engine and dynamo gives 32,000 watts, at a pressure of from 115 to 150 volts. Two Cornish boilers, 24ft. 0in. long by 5ft. 6in. diameter, work at a pressure of 100lb. per square inch. In addition to the plant illustrated, a battery of accumulators has been provided, capable of maintaining 220 60-watt lamps for nine hours, or up to 400 such lamps for a shorter period. The reconstruction of the wiring, as well as the new plant, has been arranged throughout by Mr. A. A. Campbell Swinton.

BRITISH INSULATED WIRE COMPANY (LIMITED).—We understand that this Company (the first annual meeting of which is reported in another column) intend to go in for electric light contracts, and that they have already made arrangements with the Earl of Derby to light Knowsley Hall by electricity, and that other large contracts are being negotiated. The Company in August last purchased the Ferranti mains patents for a considerable sum, and Mr. Ferranti has joined the Board of Directors, which includes many gentlemen of note in the commercial world.

FIRE.—The premises of Messrs. Hodges and Todd, electrical engineers, Verulam-street, Gray's Inn-road, were destroyed by fire yesterday morning. Business will be carried on as usual in temporary premises.

PULSOMETER ENGINEERING COMPANY.—We have received from this Company a very attractively printed pamphlet, "A Chat about a Successful Invention," which contains a quantity of information regarding the well-known Pulsometer pumps and valves, and shows the Pulsometer in use in a variety of positions and under many conditions where no other pump could be conveniently used.

PATENT RECORD.

The following list of applications for patents and specifications has been compiled for this journal by MR. J. C. CHAPMAN, *patent and registration agent, Fel. Chartered Inst. Patent Agents, of 70, Chancery-lane, W.C., from whom any available information may be obtained.*

APPLICATIONS FOR PATENTS.

NOTE.—*The undermentioned applications are not open to public inspection until after the acceptance of the complete specification. The names within parentheses are those of communicators of inventions.*

February 8, 1892.

2,365. A. F. MABON. Glasgow. Improvements in electrical communicating apparatus for mining and other works.

2,393. W. GRIGG. London. Improved method of and appliances for using electricity as a medicinal agent.

2,397. E. D. WISE. London. Electric fire-alarm.

2,401. P. GRANT. London. Improvements in incandescent lamps.

COMPANIES' MEETINGS & REPORTS.

Newcastle and District Electric Lighting Company (Limited).

The fifth ordinary general meeting of this Company was held on Monday; Mr. J. D. Milburn, Chairman of Directors, presiding.

In their annual report the Directors congratulated the shareholders on the fact that the prospects of the Company continue good. The installations connected to the mains during the year were equal to 4,000 ten candle-power lamps, bringing the total up to about 11,000, and 206,017 units of electrical energy had been supplied. The Company maintains amicable relations with its consumers, and the Directors trust that the consumption may, ere long, increase to a sufficient extent to enable them to recommend a reduction in the price of current. The gross earnings during the year amounted to £1,860. 15s., and after making provision for depreciation account and reserve fund, and writing off £200 from formation expenses, the Directors were able to recommeud a dividend at the rate of 2½ per cent. for the half-year ending December 31st, which, together with the interim dividend paid in July last, made 5 per cent. for the year.

The CHAIRMAN, in moving the adoption of the report, congratulated the Company upon the steady progress which had been made since its commencement. The receipts during the financial year ending December 31st last amounted to £4,796. 18s. 6d., as against nearly £220,000 of receipts by the Gas Company. The first time he addressed them, he, on behalf of the Directors, intimated that the Newcastle and District Electric Lighting Company did not intend to enter into any insane competition with gas. They wished to supply an artistic, healthy, and exhilarating light at a higher price than gas; and they had hitherto steadily pursued this policy with a fair share of prosperity for themselves, and with the result that, instead of doing harm to the Gas Company, its business had actually increased. They had, therefore, actually exhilarated the Gas Company; for the lighting of the City, whether by gas or by electricity, was never before so efficiently and so well done as at present. In electricity they represented the leading energy of this age, and the Directors would not be content until the Company was doing a fair share of the lighting of the City. Not only would they occupy themselves with the production of energy for lighting purposes, but they would cultivate

Digitized by Google

its use for motive power. He was convinced that as soon as they were able to show the Directors of the local tramways any advantage in the use of electricity—especially on such horse-killing places as Westgate Hill—they would not be slow to adopt it. Electric motors would also be found useful for the propulsion of machinery in its manifold uses, and he thought something more might be done by them to encourage the adoption of electric motors. The use of their plant, or a large proportion thereof, during the daytime would considerably reduce the cost of production, and render remunerative to the Company the day hours as well as the night hours, upon which they had chiefly to depend for revenue. The Directors were fully alive to the interests of the public, and so soon as the business of the Company had attained sufficient volume, and the cost of production be reduced, they would recommend a reduction in price, and so bring the use of electricity into still greater popularity. No one who had once used the electric light had any inclination to go back to gas lighting. Coming to the results of the recent year's work, he (the Chairman) said that during the past year lamps equal to about 4,000 10 c.-p. lights had been connected to the Company's mains, and during the same time 15,610 yards of cable had been laid, and 2,439 yards of main and branch piping. The 6in. main pipe, which at the commencement of the Company's operations was laid in Forth Banks, had been filled in with cable, and in view of the demands which were being received for supply of current it had been found necessary to commence laying another 6in. main.

Mr. J. B. HALLIDAY seconded the motion.

The CHAIRMAN, before putting the resolution, reminded his hearers that a great deal of their success was due to the efficient management which had been bestowed on the company by the scientific staff. With a gentleman so well versed in electricity as Mr. Parsons at their head, and officials like Mr. Hunter and Mr. Patterson, there was no wonder that good progress was made.

The report was adopted unanimously, and a vote of thanks to the chairman concluded the proceedings.

British Insulated Wire Company (Limited).

The first annual meeting of the shareholders of this Company was held in Liverpool on the 10th inst.; Mr. Marriner Briggs, Chairman of the Directors, presiding.

The Directors' report contained the following:—

"The greater part of the machinery has been delivered and erected, and the Company has commenced to manufacture cable.

"In August last the Company had the opportunity of acquiring the valuable patents for the manufacture of electrical mains and conductors of Mr. S. Z. de Ferranti, whose inventions and discoveries in electrical science are so generally known and so highly esteemed. At a special meeting the purchase was resolved upon, and an increase of the Company's capital by £50,000 duly sanctioned On the completion of the agreement for purchase Mr. Ferranti joined the Board, and his practical knowledge and experience have already proved of great value. Lucrative orders have been offered for some time past, and might perhaps have been successfully executed; but seeing that the process is an entirely new one in this country, the Directors have thought it the prudent course even to refuse orders until the machinery and testing apparatus had been thoroughly tried, and the delivery of perfectly sound material could be guaranteed. This became possible only since the beginning of this year, and the Directors have every reason to believe that the works will now be fully employed for a long time to come by the orders already given and in sight. The Directors are, of course, not able to declare any dividend, the work of the past year having been entirely devoted to the establishment of the concern.

"During the year the Board has been strengthened by the election of Mr. E. K. Muspratt, J.P., Director of the United Alkali Company, Limited, Mr. Thomas Priestly, Mayor of Bradford, Mr. J. E. Pearson, Director of the Pearson and Knowles Coal and Iron Company, Limited, and Sir David Radcliffe, Director of the Liverpool and Yorkshire Railway Company."

The report was adopted, and the retiring Directors having been re-elected, the proceedings terminated.

India Rubber, Gutta-Percha, and Telegraph Works Company (Limited).

The following is the Directors' report for the year 1891, to be presented at the twenty-eighth ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, London, on Tuesday, Feb. 23rd, at 12 noon:—

The annexed accounts show the net profit for the past year to be £79,102. 8s. Adding £39,970. 17s. 10d. brought forward, and deducting £20,800 interim dividend paid in July, there remains a disposable balance of £93,273, 5s. 10d. The Directors have added £25,000 of this balance to the reserve fund (raising it to £325,000), and recommend the distribution of a dividend of 10s. and a bonus of 5s. per share, free of income tax, amounting to £31,200, making, with the interim dividend a total payment for the year of 12½ per cent., and leaving £42,073. 5s. 10d. to be carried forward.

The increase in the sales of the Company's general manufactures continues. The cable department has been fairly well employed. More than 1,600 miles of cable have now been manufactured for the South American Cable Company; and it is expected that the whole length contracted for will be made and laid by midsummer. The efficiency of the works and machinery has been fully maintained.

Mr. Scott and Mr. Jarvis, the Directors retiring by rotation, offer themselves for re-election. Mr. Weise is re-eligible as Auditor.

Birmingham Electric Supply Company (Limited).

The following is the report of the Directors of this Company for the nine months ended December 31st last, submitted to the shareholders at the ordinary general meeting of the Company, held at the offices, 14, Dale-end, Birmingham, yesterday (Thursday):—

It will be in your recollection that the accounts presented at the first annual meeting were made up to March 31st last. The alteration of the date of closing the financial year has been adopted to accord with the requirements of the Board of Trade. The accounts submitted herewith show a profit of £713. 16s. 4d., and, taking into consideration the fact that these accounts include the supply during the six summer months, the result cannot but be deemed satisfactory. Of this sum the Directors have applied £351. 16s. 7d. to depreciation reserve account, and recommend that the balance be carried forward to next year's account.

The capital expenditure on buildings, plant, and mains, during the nine months, amounts to £7,761 16s. 7d., this sum including a battery of accumulators, and a fourth engine and dynamo.

The demand for the light has been most satisfactory. The total number of 16 c.p. lamps, or the equivalent, on order at the 31st December, being 5,480, which has since been increased by additions to 6,100. It will be of interest to note the Company have now on their books as customers two hotels, five clubs, four public buildings, two institutions, eleven restaurants, sixty shops, two banks, eight insurance offices, and fifty-six general offices.

From the very ready way in which the light has been taken up, the Directors fully anticipate a large increase in the output of the Station, and in contemplation of this they propose putting down further plant to meet such demand. It is also intended to extend the mains through a portion of the areas allotted to the Company last year.

There still remains of the Company's capital 5,625 shares unallotted, and the Directors consider that the time has arrived when it will be an advantage to the Company that these shares should be taken up. These will at once be offered to the shareholders, and afterwards to the public, at the discretion of the Directors.

Two Directors, Mr. J. F. Albright and Mr. G. H. Johnstone, retire, and being eligible, offer themselves for re-election. The auditors, Messrs. Sharp, Parsons, and Co., retire, and being eligible, offer themselves for re-election.

Westminster Electric Supply Corporation (Limited).

The following report has been issued by the Directors of this Company, and will be presented to the shareholders at the ordinary general meeting of the Company, to be held at the Westminster Palace Hotel, London, S.W., on Wednesday next, the 24th inst., at 11 o'clock:—

In submitting their report and accounts for the year 1891 the Board of Directors are pleased to state that the business of the Corporation is making satisfactory progress; for although two of the stations were not in work until the end of March, and one is still in the builder's hands, the accounts of the past year show a considerable profit upon the working, after making provision for bad and doubtful debts, allowing a fair amount for depreciation, and writing off a proportion of the preliminary expenses and suspense account.

In their report last year, the Board stated that current was being supplied to the equivalent of about 12,000 lamps of 8 c.p. At the present time current is being supplied to 67,500 lamps of 8 c.p., while applications are signed for a further 5,083 lamps of 8 c.p.

The application to Parliament for permission to supply the northern district of Westminster was successful, the Royal assent to the Bill having been given on July 3, 1891.

Mains have now been laid in all the scheduled streets throughout the area of supply, as also in every other street where the expenditure has been justified by the demand for current, both in the original and additional order. The total length of roadway along which mains have been laid up to the present date is about 31 miles. This includes a total of about 123 miles of "ways," along which 89 miles of copper have been drawn.

The Directors have every reason to believe that the Corporation's supply, which has so successfully been given to the Houses of Parliament, will be extended to other Government offices at no very distant date.

Two of the stations of the Corporation which had not been finished at the date of the last general meeting (the Mayfair Station in Davies-street and the Belgravia Station in Eccleston-place) commenced to supply current in March last, and, together with the Westminster Station in Millbank-street, have since been constantly at work. The reports from consumers and others as to the quality of the light supplied have been very gratifying and the increase in the number of applications for current received may no doubt, be ascribed to this fact.

As shown in the report accompanying the accounts the net revenue of the Corporation for the past year is £3,160. 4s. 3d., and this sum the Board consider should be carried forward.

The balance of the authorised share capital, viz.:—£85,235 in 17.047 shares of £5 each was, in accordance with the resolution of the shareholders at the general meeting in February last, issued at par, and was duly subscribed for; many of the original shareholders increased their holdings, and a number of the consumers on the Corporation's circuits invested in the shares. The whole of the authorised capital has now been subscribed, and paid up in full, and it is very satisfactory to the Board to be able to state that there is not a single unpaid call. The Directors have not made any public issue of the debenture capital for which powers are given in the Articles of Association, but have allotted £29,400 in Five per Cent. Mortgage Debentures to applicants, many of whom had applied for ordinary shares of the Corporation.

The auditors, Messrs. Cooper Brothers and Co., retire, and being eligible, offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

H. S. CROPPER AND CO. (LIMITED).—This Company was registered on February 9, 1892, with a capital of £15,000, in £10 shares, by Messrs. Hind and Robinson, 8, Stone-buildings, Lincoln's Inn, W.C. The objects are to acquire the business of ironfounders and engineers now carried on by H. S. Cropper, J. Cropper, and S. Thacker, at Minerva Works, Great Alfred-street, Nottingham; to carry on the businesses of mechanical engineers, electricians, suppliers of electricity for the purposes of light, heat, motive power, or otherwise, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity. Registered without articles of association.

PRINCESS COMPANY (LIMITED).—This Company was registered on February 12, 1892, with a capital of £2,000, in £1 shares, by W. G. MacIvy, 31, Homer-street, Marylebone-road, London, N. The objects are to carry on the business of mechanical and electrical engineers, metal founders and workers, machine and engineering tool makers, and makers of household requisites.

RUSHDEN AND HIGHAM FERRERS DISTRICT GAS COMPANY (LIMITED).—This Company was registered on February 12, 1892, with a capital of £10,000, in £5 shares, by Jordan and Sons, 120, Chancery-lane, W.C. The objects are to acquire the businesses and undertakings of the Rushden Gas and Coke Company (Limited) and the Higham Ferrers Gas and Coke Company (Limited), to light, by means of gas, electricity, oil, or other illuminating power, the streets and buildings of Rushden and Higham Ferrers; to supply heat, light, or motive power generated by gas, electricity, oil, or otherwise. Registered office: The office of Messrs. Simpson and Mason, High-street, Rushden, in the county of Northampton.

REGENERATING BOILER COMPANY (LIMITED).—This Company was registered on February 13, 1892, with a capital of £5,000, divided into 4,000 ordinary and 1,000 preference shares of £1 each, by Jordan and Sons, 120, Chancery-lane, London, W.C. The objects are: "To acquire, work, extend, develop, or otherwise, a boiler for the purpose of generating and regenerating steam, and supplying the necessary material for working and extending the same," and to acquire, work and extend any patent or patents in reference to or relating thereto, and particularly a patent now standing in the name of the vendor (Thomas White, Esq., of Thorpe Hesley, near Rotherham), and all modifications and improvements thereof. Registered without articles of association.

SEA FISHING COMPANY (LIMITED).—This Company was registered on February 13, 1892, with a capital of £10,000, divided into 9,750 ordinary and 250 deferred shares of £1 each, by J. Herbert Farmer, 35, Walbrook, London, E.C. The objects are to acquire, by way of purchase, license, or otherwise, any rights in any inventions for the purpose of fishing by the attraction of the electric light, or for any purpose in connection with fishing; and to buy, sell, manufacture, and deal in plant, machinery, implements, conveniences, &c., connected with the same.

TITANIC STEEL COMPANY (LIMITED).—This Company was registered on February 13, 1892, with a capital of £12,000, in £5 shares, by Jordan and Sons, 120, Chancery-lane, London, W.C. The objects are to acquire and carry on the business of mechanical, electrical, nautical, and general engineers, machine and engineering tool makers, iron, steel, and brass founders, boiler makers, &c., carried on by S. J. Hackney under the style of "The Titanic Steel Company" at Pott-street, New Islington, Manchester.

DIRECT UNITED STATES CABLE COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 29, 1892, was filed on February 6, 1892. The nominal capital is £1,300,000, in shares of £20 each. 60,710 of these have been taken up, all of which have been issued as fully paid. Registered office: Winchester House, 50, Old Broad-street, London, E.C.

ELECTRICITY AND ELECTRICAL ENGINEERING NEWSPAPER COMPANY (LIMITED).—The registered office of the above-named Company (which was registered on November 18, 1890, with a capital of £500, in £10 shares, to establish and work a newspaper, devoted to the interests of electrical science in all its branches), has been removed from 6, White Hart-street, Paternoster-square, London, E.C., to 34, Cannon-street, London, E.C. (filed on January 13, 1892). No returns respecting the shareholders have been filed, but the original subscribers took all the shares.

ELECTROLYTIC CAUSTIC SODA AND CHLORINE TRUST (LIMITED).—The statutory return of the above-named Company, made up to October 29, 1891, was filed on November 24, 1891. The Company was registered on June 15, 1891, with a capital of £10,000 in £10 shares, to acquire and work the British patents, Nos. 2,296 and 2,297 of 1890, being respectively patents for "Improvements in the electrolytic production of caustic soda and other products from their salts," and for "improvements in apparatus to be used for electrolytic purposes." At the time of making-up all the shares had been taken up, 500 of which had been issued as fully paid. Upon the remaining 500 £6 per share had been called and paid. Registered office: 23, Queen Victoria-street, London, E.C.

FIELD'S "M.P." DEVELOPMENT ASSOCIATION (LIMITED).—The statutory return of the above-named Company, made up to the 10th December, 1891, was filed on the 29th December following. The Company was registered on July 28, 1891, with a capital of £100,000, in £1 shares, to acquire and work certain patents (49 in all) which had been or were to be granted in Britain, Belgium, Austria, Brazil, Italy, France, Germany, Luxemburg, New South Wales, New Zealand, United States, Queensland, South Australia, Spain, Switzerland, Denmark, India, Victoria, Norway, and Sweden, to carry on the business of mechanical and electrical engineers electricians, electrical contractors, suppliers of electricity and manufacturers of and dealers in all apparatus, appliances, and things required for or capable of being used in connection with the generation, accumulation, distribution, supply and utilization of electricity. At the time of making-up, 90,000 shares had been taken up, of which £0,000 had been issued as fully paid. Upon the remaining 10,000 the full amounts per share had been called and paid. Registered office (filed on December 18, 1891): 13 and 14, Abchurch-lane, London, E.C.

FOREIGN ELECTRIC DATE AND TIME STAMP COMPANY (LIMITED).—The registered offices of the above-named Company have been removed from 90 and 91 Queen-street, Cheapside, London, E.C., to 20, Bucklersbury, London, E.C.

FREEDMAN BATTERY COMPANY (LIMITED).—The first annual return of the above-named Company, made up to January 2, 1892, was filed on January 7th following. The Company was registered on September 1, 1890, with a capital of £2,000 in £1 shares, to acquire the interests of Charles H. Freedman in an invention, particulars of which were not given, and to develop and bring into public notice the said invention. At the time of making up, 1,865 shares were taken up, 5s. per share called, and all calls paid, amounting to £466. 5s. Registered office: 66, Berners-street, Oxford-street, London, W.

S. Z. DE FERRANTI (LIMITED).—The first annual return of the above-named Company, made up to December, 12, 1891, was filed on Christmas Eve. The Company was registered on June 26, 1890, with a nominal capital of £100,000, divided into 2,000 Five per Cent. Preference and 8,000 Ordinary Shares of £10 each, to carry on the business of manufacturing engineers, contractors for the erection of central stations for the supply of electricity, suppliers of electricity, &c. At the time of making-up, all the shares had been taken up, of which 1,993 preference and 8,000 ordinary had been issued and considered as fully paid. Upon the remaining 7 preference the full amount (£70) had been called and paid. The following was filed on January 26, 1892: "At an extraordinary general meeting of the members of the above-named Company, duly convened and held at the registered office of the Company, situate at St. Benet-chambers, Fenchurch-street, in the City of London, on January 11, 1892, the following special resolution was duly passed: and at a subsequent extraordinary general meeting at the members of the said Company, also duly convened and held at the registered office of the Company on January 26, 1892, the following special resolution was duly confirmed: 'Resolved that Article 11 of the Company's Articles of Association be amended by altering the figure 5 in the third line to the figure 7, thereby providing that the preference dividend on the shares shall be at the rate of 7 per cent.' (Signed) Gerard B. Ince, Chairman." Article 11 amended now reads "Every holder of preference shares or stock shall be entitled to receive, in each half-year, a dividend upon such shares or stock after the rate of 7 per cent. per annum, and no more, out of the profits of each year, before the holders of the ordinary shares or stock shall be entitled to receive any dividend for the same year in respect of such ordinary shares or stock; and if, at the end of any current half-year of the Company's business, there are not profits available for the payment of the full dividend on the said preference shares for that half-year, the deficiency shall be made good as soon as may be out of the profits of the subsequent half-year or years." Registered office: St. Benet Chambers, Fenchurch-street, London, E.C.

W. T. HENLEY'S ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The annual return of the above-named, Company made up to January 13, 1892, was filed on January 21st following. The Company was registered on June 2, 1882, with a nominal capital of £100,000, in £1 shares, to acquire from Mr. W. T. Henley certain patents and inventions (particulars of which were not given) relating to the production, supply or employment of electricity, or electrical currents or force, and generally to produce and supply electricity. At the time of making-up 6,918 shares were taken up, the full amount called upon each share and £6,911 paid in respect of calls, leaving £7 unpaid. The sum of £41. 10s. 11d. had been paid in respect of forfeited shares. Registered office: 27, Martin's-lane, Cannon-street, London, E.C.

CITY NOTES, &c.

BABCOCK AND WILCOX (LIMITED).—The Directors have declared a half-yearly interim distribution at the rate of 10 per cent. per annum.

BELL'S ASBESTOS COMPANY (LIMITED).—The Directors have resolved to recommend the payment of a balance dividend of 7s. 6d. per share, which, with the interim dividend paid in July, makes a total distribution for the year of 10 per cent.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended February 14th were £881, as against £728 in the corresponding period of last year, showing an increase of £153. The total receipts to date, from January 1st, 1892, are £5,356, against £4,761, an increase of £595.

THE GÜLCHER (NEW) ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The following circular has been issued:—"I beg to give you notice that (the Chairman of the Company having only just returned from New Zealand) the fourth ordinary general meeting of the above Company, which stands adjourned until the 18th February instant, will be held at

Digitized by Google

the offices of the Company, Battersea Foundry, S.W., at 11 o'clock a.m. on that day, for the purpose only of being further adjourned in order that the accounts, as prepared by the auditor, may be modified, by showing in detail the result of the Chairman's visit to New Zealand upon the year's transactions. Due notice of the further adjourned general meeting will be sent, together with a copy of the accounts,—By order, T. C. MORGAN, Secretary."

NORTHERN ELECTRIC WIRE COMPANY (LIMITED).—The usual dividend of 7½ per cent. has again been declared by the Directors.

REUTER'S TELEGRAM COMPANY (LIMITED).—The final call of £2 on the 3,500 new £8 shares is due to-morrow (Saturday).

SANITAS COMPANY (LIMITED).—The Directors recommend a balance dividend of 5 per cent., making a total dividend for the year of 10 per cent.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.—The warrants for interest on the preference shares of this Company for the half-year ended December 31st last, at the rate of 6 per cent. per annum, have been posted, and are now payable at the Company's bankers, the National Provincial Bank of England, Bristol.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The receipts of this Company for the two weeks ended February 15th show a decrease of £581 as compared with the corresponding period last year.

THE ELECTRICIAN:

A WEEKLY LLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 719.—Vol. XXVIII. FRIDAY, FEBRUARY 26, 1892. PRICE FOURPENCE.
Annual Subscription (U. K.), 19/

NOTES.

By a formal announcement in the *London Gazette* of Tuesday last the scientific world is informed that it has lost a Sir William Thomson, and has gained a Baron Kelvin, of Largs, in the county of Ayr.

The speeches to which shareholders of flourishing companies are annually treated have generally the merit of lucidity, though they may lack variety. On the other hand, when a company prospers not, it is strange how little real information is given in a lengthy discourse. The shareholders of the Westminster Electric Supply Corporation are, therefore, fortunate in having heard on Wednesday afternoon a statement at the same time lucid, interesting, and free from undue vaticination as to future profits.

In February last the Westminster Company had only some 13,000 lamps connected to its mains; to-day it has no less than 72,000. Its plant, however, is well ahead of the demand, being capable of generating sufficient current for 130,000 lights; while, without enlarging the station buildings, space could be found for an additional 165,000 light plant, and without purchasing more land another 295,000 lamps could be supplied. No wonder, therefore, the chairman hails a London fog as a godsend, and gloats over the fact that the Christmas fog sent up the weekly income by 50 per cent., viz., from £800 to £1,200. For our own part, however, we hope to see the day when the Westminster Company, owing to the strain upon its ultimate resources, will anathematize a week of darkness almost as much as the rest of the community.

Mr. Powell, who temporarily occupied the chair, paid a well-deserved tribute to the energy and ability of the Company's engineer, Prof. A. B. W. Kennedy; and influenced, it may be, by the latter's references to the possibility of Mr. Nikola Tesla's experimental investigations reducing the value of the plant at Millbank, Eccleston-place, and Davies-street to that of iron-scrap, he made what our American friends would call a most "conservative estimate" as to future profits. However, taking the revenue per lamp, wired at only 10s. per annum, and supposing that no more are connected to the mains for the next twelve-months, the gross receipts may be expected to considerably exceed 10 per cent. upon the total capital expenditure, so that it is not too much to anticipate a bright future for this well managed Supply Company.

The rivals of the House-to-House Company sincerely regret the breakdown which happened last week. This Company has declared, by-the-bye, that it has neither rivals nor competitors. It takes two to make a quarrel, but a brisk rivalry and keen competition may apparently be carried on in a one-sided fashion. Be this as it may, a stoppage of supply from any of the metropolitan stations cannot but shake the confidence of the public and do temporary harm to the other companies. It would be a much greater misfortune if the electrical arrangements had been inadequate, and it is some comfort that the failure was only due to the fracture of a steam-pipe. Advocates of the low-pressure system naturally say that if batteries had been used a district would not have been thrown in darkness; but it appears that the common-sense precaution of independent supply or a ring main pipe, as adopted in all well-designed stations, would have confined the accident to one engine. We understand that the engines to which steam could be supplied after the breakage could not supply the whole load, and that a considerable part of the system was cut off until the next day, although the average per lamp may be taken as only one hour. We have heard various reports, but will merely give the information sent in reply to our inquiries by Mr. Gay:—

"We have not at any time since the station was first built had any breakdown of the electrical apparatus, but on Tuesday night last one of our steam-pipes which has not yet been duplicated developed a small fracture, and we thought it not wise to run any risk; we therefore cut off the supply to a portion of the lights. The total period during which this portion of the lights were out averages about one hour, and of course a large number were not disconnected at all."

Major Cardew's method of measuring insulation resistances, described in the present issue, appears to be an excellent one, and is certainly sensitive enough when as many as 400 cells are used for charging the quadrants. The deflection of the electrometer is proportional to the potential of the cells, and also to the difference between the voltages absorbed by the two resistances which are being compared; and it can be calculated that an electrometer, which when used idiostatically will just detect a potential of 10 volts, will be sufficiently sensitive to determine the insulation resistance to one part in 1,000. As, however, high-resistance galvanometers are much more common and much more satisfactory instruments to deal with than electrometers, it is worth while

Digitized by Google

pointing out that an electrometer is not necessary in Major CARDEW'S method, and that, in fact, the measurement can be made much more sensitive by the use of electro-magnetic instruments. An electrometer can always be replaced by a high-resistance galvanometer and a condenser, so that if in Major CARDEW'S arrangement the middle of the battery be joined to the junction of the resistances through a condenser and a Morse key, the latter being arranged to discharge the condenser through the galvanometer, the method will work equally well, and will need fewer cells than when an electrometer is employed.

THE question which was raised at the last meeting of the Physical Society about the proposed high grade of membership called "Fellows," and another class besides ordinary members, "in the shape of students," suggests that most scientific and technical societies range themselves, like transformers, into two kinds—the close and the open. The Royal Society is very properly at the head of the "close" type. The term "candidate" for election as Fellow of the Royal Society is only formal. Practically, no application is made as in other societies; but individuals are nominated by the Council, and when their names, as "selected candidates," are announced, they are for all practical purposes elected. No system could be better devised for maintaining the unrivalled position of the Royal Society. On the other hand, the qualifications for membership of the Royal Institution, Society of Arts, Physical Society, and Institution of Electrical Engineers, are equally a matter of form, for practically none are required. No distinction, under these circumstances, is carried by the fact of membership, but what may be lost to a society in prestige is amply compensated by an increased sphere of usefulness. An efficient council can take care that this freedom does not result in quantity at the expense of quality. When once the qualification is dropped or allowed, as in the case of the Institution of Electrical Engineers, to become practically nothing, a large number of members ought to support the Society, which, with so much to choose from, should have much to give. There is hardly room in any one branch of knowledge for more than a single society of the "close" type, and it seems difficult to combine the benefits which such a body affords with the wide range of the less exacting societies.

A NOTE which appears in our "Notes" column is another indication that the Chicago Exhibition is to be an excuse for the holding of innumerable Congresses. The promotion of the "progress, prosperity, unity, peace, and happiness of the world" is all very well in its way, but it is more retarded by one single act such as the MCKINLEY tariff than it is advanced by a deluge of congressional tall talk. Engineers, electrical and other, will be gathered together next year at Chicago from all points of the compass; a well-organised reception and guidance committee, and a convenient *rendezvous* for members of the same profession, would be far more appreciated by them than crowded meetings in stuffy halls, even if these miscellaneous gatherings are grandiloquently styled Congresses.

The Paris and New York Telegraph Company.—The cable of this Company is at present interrupted.

Subways.—The London County Council's Subways Bill was read a second time in the House of Commons on Monday.

"Die Elektrizität."—A new semi-monthly periodical with this title, the organ of the Leipziger Elektrotechniker-Verein, has just made its appearance.

The Oye-Fanoe Cable.—The 1891 Franco-Danish cable running between Oye and the island of Fanoe is interrupted some 45 miles from the coast of France.

Cambridge.—The Town Council last week adopted a Committee report which means the virtual abandonment of the idea of promoting the electric light by the Corporation.

Inter-urban Telephony.—The Dublin-Belfast (100 miles) telephone trunk wire has been completed, and within a few weeks Belfast will be able to speak with the Irish metropolis.

Submarine Navigation.—A new submarine vessel propelled by electricity, has been designed by Signor Pullini, of the Italian Navy, and is being constructed by that Government at Spezzia.

Belfast.—The meeting of the Gas Committee of the Corporation has arranged that a deputation representing the Corporation should proceed to London to inspect the Electrical Exhibition at the Crystal Palace.

Telegraphic Communication with Lighthouses.—Mr. Penrose Fitzgerald proposes, on going into Committee of Supply, to move a resolution with reference to telegraphic communication between lighthouses and lifeboat stations.

Royal Institution.—Mr. F. T. Piggott will deliver his Friday Evening Discourse on "Japanesque," on March 11th, in place of Prof. Oliver Lodge, who will give his lecture on "The Motion of the Ether near the Earth," on April 1st.

Personal.—Mr. Ernest G. Pink informs us that he no longer holds the post of Chief Engineer to the Electricity Supply Company for Spain, and that he has in no way been responsible for the working of the Madrid central station since November 16, 1891.

The Uses of Petroleum in Prime Movers.—Prof. William Robinson, of Nottingham, is about to deliver a course of four Cantor lectures on this subject, before the Society of Arts, on successive Monday evenings, the first lecture being on Monday next, 29th inst.

Crystal Palace Engineering Society.—On Tuesday last week a Paper was read and discussed on "Electricity as a Motive Power on Tramways and Railways," by Alfred H. C. Olley, Student, to the above society, in the new Lecture Hall of the Engineering School.

Thunderstorms.—In the West of England the recent snowstorms were in many places accompanied by thunder and lightning. At Hamerton (Devon) a carpenter, whilst on his way to his work at the Devon Great Consols Mines, was struck by lightning and killed.

Electric Traction.—At the last Town Council meeting at Mährisch-Ostran it was decided to invite tenders up to April 15th for building a tramway line, 4½ miles long, between that town, Prziwos, and Witkowitz, and also for the supply of light and power in the three places.

A "Drehstrom" Glow Lamp.—According to the *Zeitschrift für Elektrotechnik*, Messrs. Siemens and Halske have patented an incandescent lamp for use on rotating current systems. This lamp has terminals corresponding in number with the number of different phases employed.

The Electrical Utilisation of Water Power in the Tyrol.—A power station is projected on the Adige and the Toll in the Tyrol. Water power to the extent of some 10,000 horse-power is available. Light and power will be distributed in the towns of Bolzano and Merano, which are going to share the cost of the scheme.

Aberdeen.—A sub-committee of the Gas Committee of the Town Council, appointed in connection with the proposal to light the town by electricity, have resolved to obtain informa-

Digitized by Google

tion from Bradford, Liverpool, Bournemouth, Newcastle, and other places where the electric system of lighting has been in existence.

American Institute of Electrical Engineers.—With the object of calling attention to the work of this Institute, a pamphlet has been issued, giving an historical sketch of its organisation and work. Accompanying the pamphlet is an application form for admission to the Institute and a list of the officials and members.

Cable Extension.—A contract has been signed between the Portuguese Government and the Telegraph Construction and Maintenance Company, for laying a submarine cable between Portugal and the Azores, connection to be made between each of the islands of Madeira, San Miguel, and Fayal. The work has to be completed within a period of twelve months.

Bremen.—The deputation, the senate, and the citizens have at last made up their minds to accept the tender of Siemens and Halske for the erection of a central station for 20,000 lamps. The sum voted is £95,000. A 3,000-H.P. plant and a battery of Tudor accumulators for 8,000 lamps will be laid down. The three-wire mains are planned for 20,000 lamps.

The Berliner Electricitätswerke.—From this Company's annual report it appears that the number of consumers increased during their last financial year by 50 per cent.; the number of lamps connected rising during the same time from 74,959 to 104,100. The Company also experiences a good demand for current for power purposes. A dividend of 9 per cent. was declared.

Obituary.—The death is announced of Mr. Neil Bannatyne, a Director of the India Rubber, Gutta Percha and Telegraph Works Company and of the Cuba Submarine Telegraph Company. Mr. Bannatyne died at his residence, 15, Earl's Court-square, on the 15th inst. He had been connected with these two companies for twenty-two years.—The death, on the 11th inst., is also announced of Mr. Alfred Marshall, Chairman of the West Coast of America Telegraph Company.

The "Sir William Siemens" Laboratory.—On Friday afternoon last Sir William Thomson opened the Electrical Engineering Laboratory which has been founded at King's College by Lady Siemens, in memory of her husband, Sir William Siemens. The cost of the laboratory has been entirely defrayed by Lady Siemens, who has also placed at the disposal of the council of the college a sum of money to maintain it in proper efficiency. The apparatus of the laboratory includes at present a steam-engine and boiler, direct and alternate current dynamos of latest design, and a full equipment of instruments of the newest construction. The laboratory, it will be remembered, is in charge of Dr. John Hopkinson.

Mr. Nikola Tesla.—On Friday last, says our Paris Correspondent, Mr. Nikola Tesla repeated his magnificent experiments with alternating currents of high frequency before the Société Française de Physique and the Société Internationale des Électriciens. Unfortunately, Mr. Tesla confined himself to demonstrating by a series of very beautiful experiments (which it is unnecessary to describe, since they have all been published some time ago in the English technical journals) the numerous phenomena to which these currents may give rise, without either alluding to his methods of obtaining these high frequencies, or giving the audience the benefit of his own personal explanation of the phenomena. An exchange of ideas on the question would, however, have been much appreciated. Mr. Tesla was, nevertheless, warmly congratulated on his experimental skill.

Lightning Statistics.—For some time past M. Évrard has annually published in the *Bulletin de la Société Belge d'Electriciens* a statistical *résumé* of the lightning strokes which have occurred in Belgium. These statistics are very exhaustive, and have proved of considerable scientific and practical value. The Société Belge d'Electriciens are, therefore, agitating for the creation of a permanent Lightning Rod Commission, to collect, edit, and publish these statistics as hitherto, and to study the whole theory of the subject in the light of actual phenomena. The Société ask that M. Lancaster, who is at the head of the Belgian meteorological service; M. Lambotte, telegraph engineer; and M. E. Lagrange, secretary of the Société, should be members of the Commission. The Académie Royale having given the proposal every support, it is expected that the Commission will be formed.

An American Street Railway Engine.—There has, says the *Electrical Engineer* of New York, been recently installed in the power house of the Buffalo Railway Company the first of two engines which have been specially designed for electric railway work. The engine is of the vertical 2-crank compound condensing type, with cranks at 90 degrees to facilitate starting and stopping. It drives two Edison railway generators by means of two 24in. belts from the fly-wheel of the engine, which is 12ft. in diameter and weighs 16 tons. The total weight of engine is about 40 tons. The engine runs at 138 revolutions, with a piston speed of 600ft. per minute; on 125lb. initial pressure the engine develops 450 H.P. The speed is regulated by means of a centrifugal shaft governor. Operated in this manner the speed varies only by ½ revolution in a change of load from 360 to 700 amperes.

The Cologne Municipal Central Station.—The number of houses connected to the municipal network, says our German correspondent, is now about 150, with a total of 20,000 8-c.p. lamps installed. The maximum demand in December and January was equivalent to about 11,000 8-c.p. lamps. The increasing demand has made it necessary to order a third 500 H.P. steam dynamo from the Helios Company of Cologne and Messrs. Sulzer. Only 3 per cent. of the lamps installed are in private houses, the others being chiefly in shops, and a few hundred also in public buildings. To encourage the public the charge of 1d. per 100 watt hours has been reduced, in such a manner that of two consumers with a different number of lamps installed, but with an equal monthly consumption, the one with the smaller installation will have the benefit. The consumer may also now instal as many lamps as he likes without being bound to burn them a certain number of hours yearly; at first he had to guarantee 300 hours per lamp installed. The horizontal Sulzer engines illustrated in *The Electrician*, November 13th, 1891, p. 35, requires only 2·2lb. of coal per I.H.P.H. The financial aspect of the station is most encouraging.

The Recent Magnetic Storm.—The recent magnetic disturbances were by all reports widespread and unusually severe. M. Moureaux informed the Académie des Sciences, at its last meeting, that "An extraordinary magnetic disturbance, such as has not been observed for ten years, surpassing in its intensity that of November, 1882, was registered on the magnetograph of the Parc Saint-Maur Observatory on February 13th and 14th. It began suddenly about 5:45 a.m. on the 13th by a simultaneous increase of the declination and horizontal component, and a corresponding decrease of the vertical component." As at Kew, the curves went off the scale. The disturbance ceased about 5 p.m. on the 14th. The total variation of the declination was more than 1° 25′, and the horizontal and vertical components varied from their normal values by $\frac{1}{3\cdot7}$ and $\frac{1}{3\cdot8}$ respectively. The curves at Perpignan, Lyons, and Nantes show that the phenomenon began at the same time, and the variations at the four stations are so similar that the records of the instruments are as superposable as tracings of a drawing. The disturbance, says M. Moureaux, is clearly distinguished from all others recorded at the Parc Saint-Maur Observatory by the excessive variations of the vertical component.

The Protection of Buildings from Lightning.—A Paper on this subject was recently read before the Society of Architects by Mr. Alfred Hands. Between April 1st and October 31st, 1891, the following buildings were stated to have been struck by lightning, and more or less damaged:—Churches and chapels, 21; residences, 114; farmhouses and ricks, 28; hotels and public-houses, 9; schools, workhouses, and other institutions, 7; factories, mills, and other business premises, 9; chimney shafts, 5; railway stations, 3; military buildings, 2; telegraph and post offices, 2; stables, 3; race stand, 1; athletic pavilion, 1; lifeboat house, 1. The loss of life by lightning during the same period includes:—Men and women, 18; cattle, 94; horses, 35; sheep, 153. Mr. Hands is of opinion that quite 70 per cent. of the conductors now in England are in an unsatisfactory condition. In stating that at least 70 per cent. of the lightning conductors in England are in an unsatisfactory condition, Mr. Hands does not include

Digitized by Google

the magazines, &c., of the War Department, the majority of which are provided with extensive systems of conductors, which are tested annually and kept in good order. The list of buildings damaged by lightning, consisting of 206, is not by any means a comp'ete one, as it only includes cases extracted from the public Press.

Telephonic Progress in Austria.—An occasional correspondent sends us the following particulars with regard to telephonic matters in Austria:—The telephone continues to make steady progress. The subscribers in Prag, Trieste, Lemberg, Graz, Czernowitz, Pilsen, Reichenberg, and Bielitz, have increased to 3,624, and in Vienna to 5,200, and in the 47 small exchanges opened by Government since 1889 to 1,716, a total of 10,540. In Vienna the majority of the lines are underground looped lines; reckoning these as single, there are now 12,250 miles laid, and 9,500 being laid. The total telephonic wire mileage for the country amounts to 25,800. The cables used in Vienna are 1mm. copper wire, covered with 1mm. gutta-percha. There is only one exchange in Vienna into which now 5,000 looped lines run, and about 3,000 more are being run into it to provide for future extensions. The most distant subscriber is some four miles from the exchange. Interurban trunk lines have also been pushed forward; there are now 23, of which the most important are:—Vienna-Prag (direct), 191 miles; Vienna-Prag (*viâ* Brünn), 219 miles; Vienna-Brünn (direct), 79 miles; Vienna-Budapest (three lines), 25 miles; Prag-Tilschen, 72½ miles; Prag-Reichenberg, 70 miles. The Vienna-Trieste line will be commenced in March *viâ* Graz; it will be 313 miles long.

Chicago Exhibition.—The British railways have undertaken to carry goods for British exhibitors at the Chicago Exhibition, to and from the port of shipment, at half rates. The American railways will charge their usual rates to Chicago, but will bring back the goods free at the close of the Exhibition. Many of the principal steamship companies have reduced their rates considerably, and will take freight for the Exhibition at 11s. per ton. Many of them have also consented to adopt a reduced passenger tariff for exhibitors and their *employés*, certified as such under the authority of the Royal Commission.——Among the various Congresses which are being promoted by the "World's Congress Auxiliary" is an International Congress of Engineers. Its organisation has been entrusted to a special committee, assisted by an Advisory Council, of which Mr. James Dredge, Mr. W. H. Maw, and Sir Benjamin Baker are members. It is expected that the Engineering Congress will take place in the month of July or August. The Congress is to begin with a joint meeting, and it is then to be divided into seven general divisions, as follows:—(A) Civil Engineering, (B) Mechanical Engineering, (C) Mining Engineering, (D) Metallurgical Engineering, (E) Electrical Engineering, (F) Military Engineering, (G) Marine and Naval Engineering. Voluntary Papers are to be solicited from engineers throughout the world. Some of the objects of this organisation are, we are told—(I.) To provide for the proper presentation of the intellectual and moral progress of the world, in connection with the Columbian Exposition of 1893, in a series of World's Congresses under the auspices of the Auxiliary, with the assistance of the leaders in all the chief departments of human achievement. (II.) To bring all the departments of human progress into harmonious relations with each other in the Exposition of 1893; to crown the whole glorious work by the formation and adoption of better and more comprehensive plans than have hitherto been made to promote the progress, prosperity, unity, peace, and happiness of the world; and to secure the effectual prosecution of such plans by the organisation of a series of world-wide fraternities through whose efforts and influence the moral and intellectual forces of mankind may be made dominant throughout the world.

Electric Current for Medical Purposes.—In a recent article in the *Lancet*, Dr. W. S. Hedley briefly discusses the precautions necessary when using current "from the main" for electro-medical purposes. If the current supplied, he says, be the continuous one, an adjustable rheostat is all we require, provided we keep a milliampere meter, or at least some current measurer, in circuit. Such rheostat ought to possess quite 50,000 ohms resistance, working down by steps not exceeding 1,000 at a time to zero. The objection to such an arrangement is that in the event of the electromotive force in the mains rising suddenly from some disturbing cause, the safety-fuse may act, and (automatically cutting off the current) give a more or less violent shock to any patient under treatment at the time. Further, that if, as sometimes happens, the fuse is somewhat sluggish in its action, a current considerably in excess of that intended may pass through the patient for the instant previous to the automatic breaking of the circuit. In a well-regulated current supply, such as that now provided by our English electric light companies, the risk of accidents of this nature, Dr. Hedley thinks, is very small. Still, it is well to bear in mind that in using a current from an electric light main we must be prepared against an unexpected and undesirable *increase* of power, instead of the unexpected, undesirable, and vexatious *decrease* of power which frequently accompanies battery currents. Dr. Hedley then refers to the use of alternate currents, and the ease with which they lend themselves to various transformations. He also points out that the varying currents obtained from the main of an electric light supply company do not vary so abruptly as those generated by an ordinary medical induction coil, and their medical *qualities* are, therefore, not quite the same. The current from an alternator is, as Dr. Hedley correctly states, "*comparatively* smooth and wavy," though it is scarcely of the pure sinusoidal order that he assumes. Dr. Hedley concludes that whilst it is clear that electric light circuits cannot be used for medical purposes without the strictest measures of precaution against the influx of strong currents, there is also good reason to suppose that efficient protection can be secured by the adoption of suitable methods.

The Buffalo (N.Y.) Arc Light Stations.—The National Electric Light Association holds its semi-annual meeting at Buffalo this week, and the *Electrical World* of February 13th contains a sort of electrical guide-book to Buffalo, compiled by Mr. Carl Hering. The following particulars relating to the Brush arc-light central station are interesting. The station has at present a capacity of 1,000 lights, and is run by a single tandem-cylinder condensing engine of the Reynolds-Corliss type. The coal consumption is 1·93lb. per light per hour. At present one Weston, one 100-light Wood, and eighteen 60-light Brush dynamos are in use. The Brush 60-lighters are, however, considered too small, and twelve 100-light 5,000-volt Wood dynamos are to be added. The longest circuit is 21 miles in length. The entire station is run by five men, viz, two firemen, one engineer, one oiler and one dynamo-tender. A recent addition to the station is a line of compressed air piping. This compressed air performs the double function of blowing out commutator "arcs" and cleaning the dynamos. An interesting feature of the Thomson-Houston station at Buffalo is the use of the exhaust steam for heating buildings in the vicinity. Formerly the steam was discharged directly into pipes, which, however, necessarily caused a back pressure. They are replacing this system now by the Bernard vacuum system, in which there is a condenser at the return end. The advantage of this is that there is no back pressure and that they get the benefit of the hot water from the return pipes, which, however, is limited to that from the buildings which are higher than the station, as the water returns by gravity; in low buildings the water is discharged. The disadvantage of the vacuum system is that it requires a return system of piping. The charges are 25 to 30 cents per year per square foot of radiating surface of the heater. They are very well satisfied with the system and find it an excellent investment. They limit the amount to that which they can supply with the exhaust steam only. They are about to introduce a 5lb. cold air blast service at this station also, the escape being directed to the armature. Our readers must not imagine that this is for the purpose of blowing out the spark on the commutator; for Mr. J. Stanford Brown wrote (*The Electrician*, December 4, 1891) to say that the air blast of the Thomson-Houston dynamo was never intended for the purpose of blowing out the spark, but that the idea was "simply to blow a cold blast of air, as it were, to drive that spark away," &c. This important distinction was lost sight of by Prof. S. P. Thompson and others.

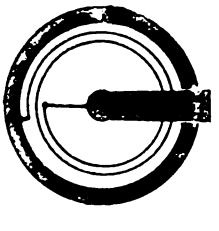
ELEMENTARY IRONLESS DYNAMO.

BY S. TOLVER PRESTON.

The mention of the idea of an ironless dynamo in the Physical Society's report in *The Electrician* of January 29th, makes me think of a suggestion in a Paper of mine in the *Philosophical Magazine* for July, 1871. I give in the accompanying sketch an arrangement which would seem (query) the most elementary form conceivable, more so than that proposed in the above Paper. The chief idea therein (which, if not new, was at least original) was that the machine should—after the instantaneous introduction of an initial current* into the circuit by the temporary approach of a magnet, &c.—keep up by the reaction of its moving parts a current: in other words, that electricity or current should be generated out of *mere motion*.

The apparatus consists of a metal ring (shown black in the diagram) simply used for a brush or radial arm to slide on. One end of a short spiral of wire is attached to the ring outside, the other end to a central pivot or axis carrying the radial arm or brush. This is all. The brush can spin round like the spoke of a wheel in sliding contact with the surface of the ring. It may be an interesting question as to what is the limiting velocity required to keep up a current, in view of the simplicity of the apparatus.

The machine resembles in principle a known form of motor for illustrating the mutual reaction of currents; and if a voltaic element were introduced into the circuit of the machine (by interrupting the spiral at any point and attaching screw terminals), the radial arm could of course be made to rotate by the action of the magnetic lines of force of the spiral, which the arm cuts transversely.



If (conversely) the radial arm be forced to revolve in the direction opposite to that in which the current tends to drive it, the current will be intensified, or mechanical energy converted into current. By an adequate increase of velocity of impressed spin, it is evident that the current generated by the reaction of the moving parts of the circuit upon each other will enormously exceed that of the voltaic element, which may consequently be shunted out of the circuit without making any practical difference in the current, which the machine evolves *solely out of motion*. But it appears a limiting velocity is required to keep it going. We may observe that the machine represents practically a self-charging dynamo on the Siemens-Wheatstone principle, but carried a step further on account of the entire absence of magnet or iron. What is called the Siemens-Wheatstone principle, whereby a current from a revolving armature is turned into the coils of the electro-magnet to augment its magnetism and so react again (strongly) on the armature—is then analysed, a motor reversed (*i.e.*, driven instead of driving), or nothing more, as will probably be admitted. In fact, without altering the arrangement of the connections, put a voltaic battery into the circuit of such a machine, and it revolves. Leaving the battery in, drive the machine in the reverse direction to that in which the current twists it, and we raise current to any intensity; so that the machine is a reversed motor. Without changing the connections, merely short-circuit the battery, and the current derived from rapidly reversing the machine remains practically the same. The above discovery (ingenious as it is admitted to be) amounted to observing that when a motor is itself driven instead of driving something, the residual magnetism in the iron will render superfluous a voltaic battery to start the machine into electric activity.

* This is, of course, parallel to the way in which electrostatic influence machines are excited.

The introduction of a voltaic cell into the circuit of our elementary machine (without iron) was only imagined for the purpose of illustration. Theoretically, all that is necessary, of course, is to approach to the spinning apparatus a magnet or a separate current for an instant. The initial current induced in the revolving radial arm is then immediately intensified by the reaction of the moving parts of the circuit upon themselves (according to the compound interest law), increasing the magnetism of the spiral, and so the effect *ad infinitum*, i.e., dependent on the velocity, as we may remark. If the speed demanded be impracticably great a purely theoretical interest will attach to the subject. The opposition of centrifugal force or friction, if too excessive, cannot alter the truth of the idea, obviously.

Hamburg, Feb., 1892.

THE D.P. ACCUMULATOR.

Much has been heard of late about the D.P. or Dujardin-Planté accumulator, which is now being regularly manufactured by Messrs. Johnson and Phillips for Messrs. Drake and Gorham, who hold the English patents for the original cell, and the numerous improvements in detail which they have introduced

Unformed D.P. plate.

since this accumulator first came into their hands. Some Dujardin-Planté plates were shown at the St. Pancras Vestry Electrical Exhibition in March last, and attracted much attention; but we were unable at that time to elicit any information with regard to their peculiarities and performance beyond what we could see for ourselves (*The Electrician*, Vol. XXVI., p. 612).

These cells, we are now informed, may be considered to have got beyond the experimental stage, having been in actual commercial use for the last two years. There is a decided tendency, on the part of the leading storage-battery makers, to a reversion to the old Planté type, and the Dujardin plate is no exception to the rule; it is, indeed, essentially of the Planté type, no oxides or salts of lead being used in the course of manufacture. From the accompanying illustration of an unformed D.P. plate, it will be seen that it is laminated in structure, being composed of thin strips of sheet lead built up one above the other, and burnt on to lead supports at either end. Spaces are left between the strips in which oxides are formed, by a modification of the Planté process. A plate of this character obviously offers a large working surface, and is free to expand in a vertical direction. By using very thin strips, a remarkably high capacity per lb. of plate can be obtained, though of course at the expense of other equally-important qualities, such as durability.

The following figures with regard to the capacity, normal rate of charge and discharge, &c., which have been furnished us by Messrs. Drake and Gorham, will be of interest:—The capacity per lb. of plate (both positive and negative) at the standard discharges is about 4·5 ampere hours. This, as we have stated above, can be greatly increased if necessary in special types of cells, such as for tramcar work, &c., by increasing the number of strips in each plate and making them thinner. The normal rate of charge is about ·071 ampere per

Digitized by Google

square inch of positive plate, or ·034 ampere per square inch of both plates, or half these figures if the two surfaces of each plate are considered. The normal discharge current is the same. The maximum discharge current per square inch of positive plate is about ·068 ampere per square inch of positive and negative plate, or half these rates if both sides the plates are considered. The normal discharge per lb. of positive plate is at the rate of ·95 ampere, and per lb. of positive and negative plate ·44 ampere. The maximum discharge per lb. of positive plate is 1·9 ampere, and per lb. of positive and negative plate ·88 ampere.

The acid used is the ordinary commercial sulphuric acid at a specific gravity of about 1160. The distance between the plates in the standard type cells is $\frac{5}{16}$in. The sizes of plates in the standard type cells are—positives 9½in. by 9in. by $\frac{5}{16}$in., negatives 10in. by 9in. by ¼in.; the positives being made slightly narrower than the negatives to give them perfect freedom to expand in any direction, thus avoiding all risk of buckling. The plates are connected in the ordinary way by burning them in parallel on to a common lead strip arranged to bolt on to the adjoining cells. The sections are stood on V-shaped bottom blocks leaving a clear space of from 1½in. to 2in. between the section and botton of the cell, for the collection of mud, paste, &c. The capacity of these cells is said to be considerably higher for rapid discharges than that of other types. Discharging the cells at double the list rates only decreases the capacity by about one-third.

On the Continent the leading type of cell is undoubtedly that known as the Tudor, and as the Planté principle enters largely into its construction the following comparative figures are serviceable :—In the D.P. cell we get 2·44, and in the Tudor 1·83 ampere-hours per lb. of total weight of cell of 220 ampere-hour capacity; in the D.P. cell the normal discharge current in amperes per square inch of plate is ·034, in the Tudor ·03.

A battery of D.P. cells was at work throughout the whole of the Naval Exhibition in connection with Lieut. Wells's exhibit, and its performance was satisfactory to him, although the battery worked under exceptionally trying conditions. A special pattern has been designed for central station purposes, and is now to be seen at the Crystal Palace.

THE ELECTRICAL EXHIBITION AT THE CRYSTAL PALACE.

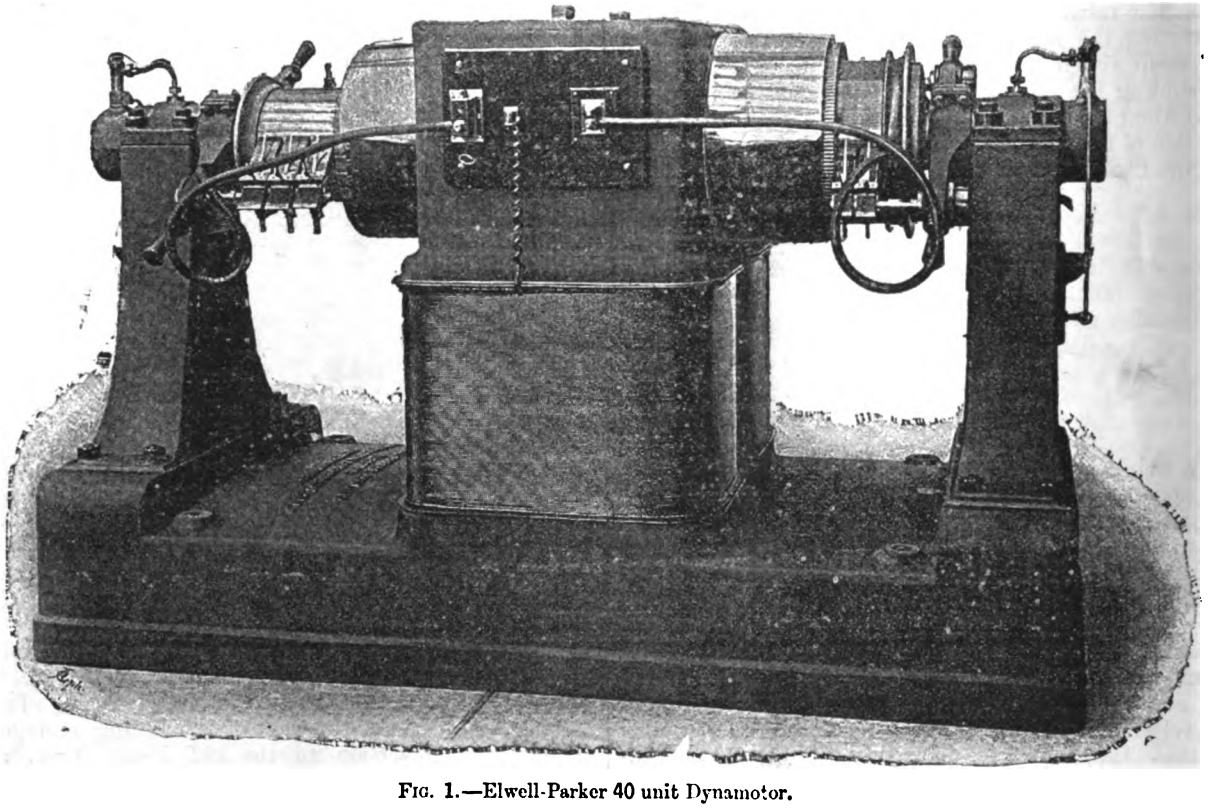


Fig. 1.—Elwell-Parker 40 unit Dynamotor.

The Electric Construction Corporation exhibit an Elwell-Parker continuous-current transformer, which supplies current to various exhibitors. This machine (Fig. 1) is wound to give an out-put at the secondary terminals of 110 volts and 360 amperes, when supplied with primary current from Messrs. Gordon and Co.'s station at Sydenham, at a pressure of 1,000 volts, and run at a speed of 550 revolutions per minute. The efficiency is as high as 91 per cent. with full load, and over 81 per cent. down to one-third load. The bearings are fitted with specially designed oil pump so as to secure continuous lubrication, allowing the machine to be left for lengthened periods without attention. A similar machine to this has been running at the Chelsea Electricity Supply Company's station for the last eighteen months, and recently a second one has been added. The Corporation now have in hand a complete central station for Oxford, where high-pressure continuous current with the Elwell-Parker transformers has been adopted.

Messrs. Woodhouse and Rawson exhibit a large collection of their well-known goods. Among a number of new arrangements of telephones is a very convenient one in which an office inkstand is fitted with a small transmitter and receiver (Fig. 2).

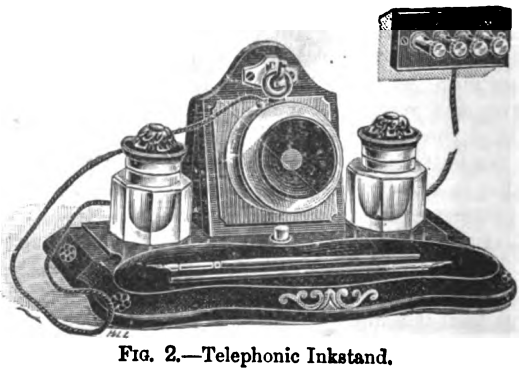

Fig. 2.—Telephonic Inkstand.

A switchboard for use with compound-wound motors is exhibited by this firm (Fig. 3). Four switches are arranged on the board, respectively for excitation, main circuit, resistance, and

Digitized by Google

reversing of the series-wound field. The series-winding, which in a compound motor necessarily opposes the field produced by the shunt, in order to produce compounding, is a hindrance to the development of a strong field and powerful torque at starting. In the above arrangement the series-winding is made to contribute to, instead of detracting from, the torque at starting, by utilising the coils reversed. As soon as the motor has attained its speed the coils are reversed again to perform their compounding action. The switches on the board referred to above are provided with locking cams, which effectually prevent the switches being turned in any other but their proper order. Thus the main current cannot be switched on to the motor until the shunt field switch is closed and the motor is fully excited. Similarly the main current cannot be switched on unless the resistance switch is at its highest point.

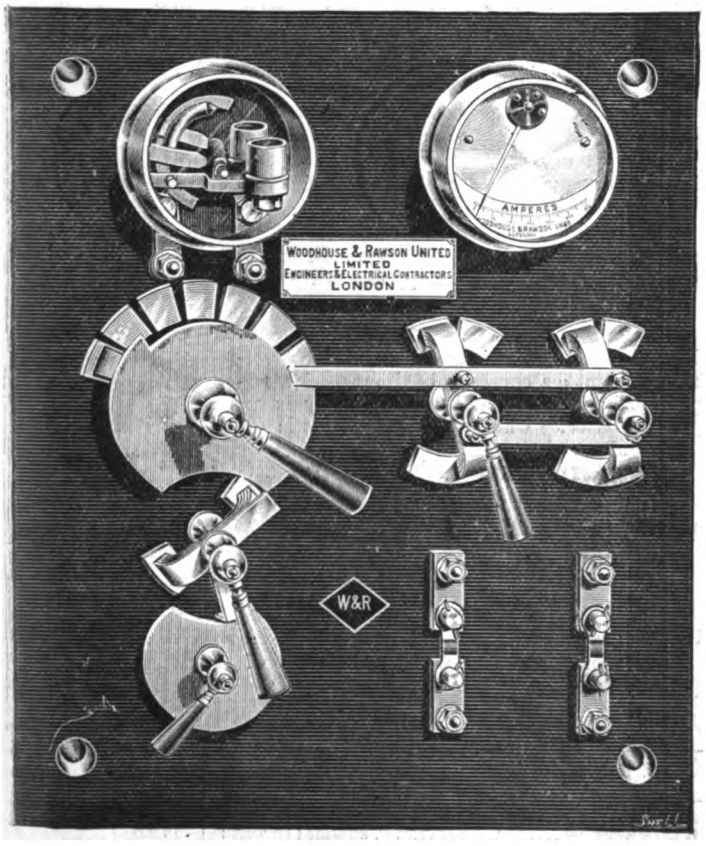

FIG. 3.—Switchboard for Compound-wound Motors.

After the motor is started and the resistance is gradually reduced, it is impossible to take all the resistance out until the switch controlling the series-winding is put back so as to bring the coils into their right direction for compounding. It is by such carefully thought-out arrangements as these that the cost of maintenance may be minimised by enabling the apparatus to be safely controlled by an unskilled attendant.

REVIEWS.

The Universal Office Manual. By OXBARROW AND MONEY-KENT. (Wightman and Co., 31, Victoria-street, S.W.)

This is a work designed to assist those who are not fully acquainted with the routine of counting-house work. The book consists of about 120 large oblong pages, and contains a number of special rulings for counting-house books, with printed examples of many special varieties of book-keeping, and will doubtless be most acceptable to many persons to whom the mysteries of book-keeping form one of the most difficult features in their every-day work. In addition to the rulings referred to a glossary of business terms is given. The book is well got up, and should prove to be of great use.

ON THE LAW OF HYSTERESIS.*

BY CHAS. PROTEUS STEINMETZ.

(*Concluded from page 410.*)

Magnetometer Tests.

The method used in the foregoing has the great advantage that

1. It allows the taking of a greater number of readings, over a wide range of magnetisation, in a short time, by mere simultaneous instrument readings, and thereby reduces the probable error by increasing the number of observations.

2. It allows the use of electro-dynamometers, as the most reliable electric measuring instruments.

3. It deals with larger amounts of energy, counting by watts or even hundreds of watts, whereby a much greater accuracy can be reached than by the ballistic galvanometer.

4. It measures the hysteresis under the influence of an harmonically, and not suddenly varying, M.M.F., that is under the same conditions, where it becomes of importance for practical engineering.

But it has the great disadvantage that it can be used only for testing sheet-iron or other thoroughly-laminated iron, where eddies are either inappreciable or can be calculated. For testing solid iron and steel pieces, this method cannot be used, because of the tremendous amount of eddies which would flow in a solid piece of iron.

To determine the hysteretic loss of energy in steel and cast-iron the Eickemeyer differential magnetometer was used. Complete description of this instrument and its use is to be found in the *Electrical Engineer* of New York, March 25, 1891. An exhaustive series of experiments were made with this instrument on several kinds of iron. The results are briefly summarised in the following tables :—

TABLE V.—*Magnetic Characteristic.*

F in ampere turns per centimetre length of magnetic circuit.

$H = 25{,}000$; alternate current transformer, American style (high frequency).

$H = 35{,}000$; alternate current transformer, European style (low frequency).

Only the values smaller than ·25 W, can be of practical use ; in those larger than 10 the iron gets at least red hot if in larger quantities.

"remanent" magnetism is still in the saturation part of the curve—that is, in stable equilibrium ; therefore permanently magnetisable.

2. The soft iron curve, with the bend on the *positive* side, so that for zero M.M.F. the "remanent" magnetism, though still very high, is already below the range of saturation, on the branch of unstable equilibrium. Therefore, the remanent magnetism is very unstable and easily destroyed, the more as the coercitive force is very small.

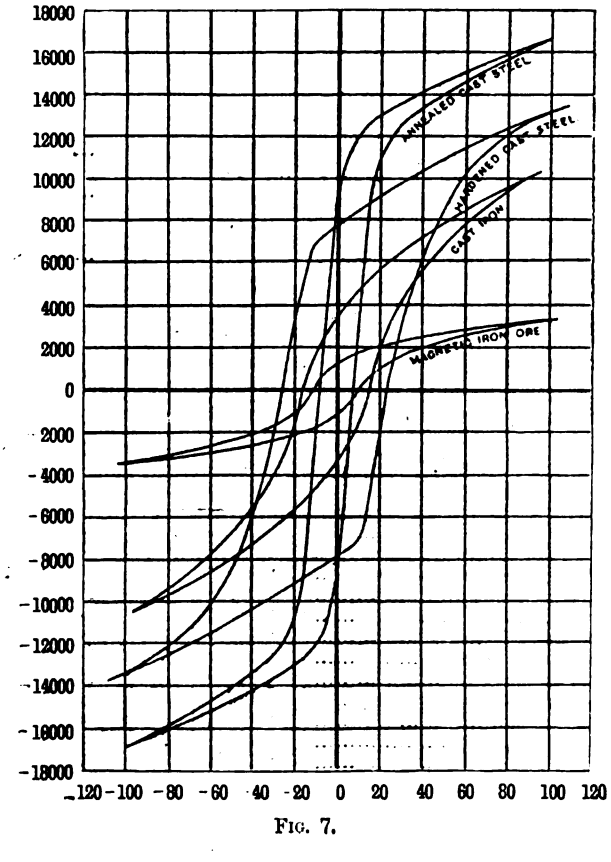

FIG. 7.

3. The cast-iron curve, which has no marked knee at all, but a steady curvature of low remanent magnetisation, but with regard to coercitive force ranging between 1 and 2.

The curve of the magnetic iron ore shows all the characteristics of a cast-iron curve.

Having derived, now, a larger number of values of the hysteretic coefficient η for different kinds of iron and other material, we shall put them together for comparison in Table VI.

For convenience, in Table VII. are given the values W of consumption of energy in watts per cubic inch for 100 complete periods (magnetic cycles) per second, and for the magnetisation of H lines of force per square inch, giving as coefficient of hysteretic resistance the value $\gamma = 8{\cdot}3 \times 10^{-6} \eta$.

In this Table I have given a number of experimental values of the consumption of energy by hysteresis, and believe to have shown that this consumption of energy can fairly well be expressed by the empirical formula,

$$H = \eta \quad ^{x}$$

where the exponent x is equal, or at least very nearly, to 1·6, and the coefficient η a constant of the material, which ranges from ·002 up to ·025 and more, and may possibly have a slight dependence upon the *velocity* wherewith the magnetic cycle is performed, as the second set of alternate-current readings seems to indicate.

In Table VIII., I give the values of the hysteretic resistance η for some iron samples, subjected to a magnetic cycle between $F = +190$ and -190 ampere turns per centimetre, calculated from Hopkinson's tests * by the assumption of the law of hysteresis.

η denotes the coefficient of hysteresis.

B the maximum magnetisation in lines of magnetic force per square centimetre.

R the remanent magnetisation in lines of magnetic force per square centimetre.

These values of the hysteretic resistance vary from ·002 up to ·082, 41 times the first value.

But especially marked is, that η depends much less upon the chemical constitution of the iron sample than upon its physical condition, *annealing decreasing* and *hardening increasing* the hysteresis very considerably.

* From "Kalender fur Electrotechniker," by Uppenborn, Berlin, Germany.

Digitized by Google

So far as the chemical constitution is concerned, the purer the iron the lower is its hysteresis, while any kind of foreign matter increases the hysteresis. Especially manganese increases the hysteretic loss enormously, much less wolfram and chromium, least silicon and carbon. Connected with the increase of hysteresis is always a decrease in susceptibility.

To combine the results, what I believe I have proved is that loss of energy in iron caused by reversals of magnetism can be expressed by the analytical formula

$$H = \eta B^{1.6} + \epsilon n B^2$$

where η is the coefficient of hysteresis, ϵ the coefficient of eddy currents, n the frequency of the alternations of magnetism, $\eta B^{1.6}$ the loss of energy by hysteresis proper, or by *molecular friction*, and $\epsilon n B^2$ the loss of energy by eddy currents, per magnetic cycle and per cm.^{3}, proportional to the frequency n.

PHYSICAL SOCIETY.

At the annual general meeting of this Society on Friday, February 12th, Prof. W. E. Ayrton, F.R.S., President, in the Chair, the report of the Council was read by the President, as were also the obituary notices of Prof. W. Weber, late honorary member, Mr. W. G. Gregory, and Prof. James Crouch Adams.

The following gentlemen were declared duly elected to form the new council :—President : Prof. G. F. Fitzgerald, M.A., F.R.S. Vice Presidents : Prof. A. W. Rücker, M.A., F.R.S. ; Walter Baily, M.A. ; Prof. O. J. Lodge, D.Sc., F.R.S. ; Prof. S. P. Thompson, D.Sc., F.R.S. Secretaries : Prof. J. Perry, D.Sc., F.R.S., 31, Brunswick-square, W.C., and T. H. Blakesley, M.A., M.Inst.C.E., Royal Naval College, Greenwich. Treasurer : Dr. E. Atkinson, Portesbery Hill, Camberley, Surrey. Demonstrator : C. Vernon Boys, F.R.S., Physical Laboratory, South Kensington. Other members of Council : Mr. Shelford Bidwell, M.A., F.R.S. ; Dr. W. E. Sumpner, D.Sc. ; Major-General E. R. Festing, R.E., F.R.S. ; Mr. J. Swinburne ; Prof. J. V. Jones, M.A. ; Rev. F. J. Smith, M.A. ; Prof. W. Stroud, D.Sc. ; Mr. L. Fletcher, M.A., F.R.S. ; Dr. G. M. Whipple, D.Sc. ; Mr. James Wimshurst.

The CHAIRMAN having invited suggestions towards improving the working of the Society,

Prof. S. P. THOMPSON said that as the Society had been established fifteen or sixteen years and had amply justified its existence, the time had now arrived for giving fuller recognition to the privileges of members. He thought they had earned the right to be called "Fellows," and that this ought to be signified by some distinctive title.

Mr. J. SWINBURNE suggested that before Papers were brought before the meetings they should be read by a member of Council. If suitable they should then be printed, and proofs sent to members who applied for them. Mathematical Papers could then be taken as read, and the discussions would be more interesting and to the point. It would also be an advantage if communications on kindred subjects could be taken the same day and discussed together. Papers on purely technical subjects should go to the Technical Societies.

Prof. AYRTON, in reply to Mr. Swinburne, said the members had the matter of Papers in their own hands, for, as pointed out in the Report of the Council, if they would only send in the Papers early enough the secretaries would be glad to group them in the way suggested. Referring to Prof. Thompson's remarks, he said he had often thought it would be an advantage to have another class of members in the shape of "Students," who should hold meetings amongst themselves.

Mr. A. P. TROTTER said the Society was unique in many respects, and he thought it was not desirable to have different grades of membership.

Dr. C. V. BURTON agreed with Mr. Trotter, and said that even if Prof. Thompson's suggestion were adopted, means should be provided that persons could be admitted into the Society without claiming any distinction therefrom.

Prof. S. P. THOMPSON referring to the communications brought before the Society, said it was not necessary that all should possess great novelty. Descriptions of new arrangements of apparatus, of diagrams, and exhibits of modern instruments were of great interest to members.

The CHAIRMAN pointed out that at the early meetings of the Society exhibitions of instruments were frequent, and said the Council would be glad if instrument makers would send apparatus to be shown at any of the meetings.

The meeting was resolved into an ordinary Science meeting, and Prof. S. P. THOMPSON, F.R.S., communicated a "Note on Supplementary Colours," and showed experiments illustrating the subject.

A Paper "On Modes of Representing Electromotive Forces and Currents in Diagrams," by Prof. S. P. Thompson, was postponed.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-DAY) FRIDAY, February 26th.

PHYSICAL SOCIETY.

5 p.m. Papers to be read : (1) "On Modes of representing Electromotive Forces and Currents in Diagrams." By Prof. S. P. Thompson, F.R.S. (2) "On the Flexure of Long Pillars under their own Weight." By Prof. Maurice FitzGerald, M.B. (3) "On Choking Coils." By Prof. J. Perry, F.R.S.

INSTITUTION OF CIVIL ENGINEERS.

7:30 p.m. Students' Meeting. Paper to be read : "The Construction and Efficiency of Locomotive Boilers." By G. H. Sheffield, Stud.Inst.C.E.

ROYAL INSTITUTION.

9 p.m. Evening Discourse : "Optical Projection." By Sir David Salomons, M.A.

SATURDAY, February 27th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture : "Matter at Rest and in Motion." By Lord Rayleigh, F.R.S.

MONDAY, February 29th.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. III.—1. "The Uses of Petroleum in Prime Movers." By Prof. William Robinson, Assoc. M.Inst.C.E.

TUESDAY, March 1st.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Papers to be discussed :—(1). "The Bishop Rock Lighthouses." By W. T. Douglass, M.Inst.C.E. (2). "The Illumination by Gas of Tory Island Lighthouse, Co. Donegal." By David C. Salmond, Assoc.M.Inst.C.E. At this Meeting the Monthly Ballot for Members will be taken.

WEDNESDAY, March 2nd.

SOCIETY OF ARTS.

8 p.m. Ordinary Meeting. "Spontaneous Ignition of Coal and its Prevention." By Prof. Vivian B. Lewes.

THURSDAY, March 3rd.

INSTITUTION OF ELECTRICAL ENGINEERS.

8 p.m. Ordinary General Meeting.

CHEMICAL SOCIETY.

8 p.m. Ordinary Meeting.

FRIDAY, March 4th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Ladies' Night. Concert at St. James's Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse : "The Surface-Film of Water, and its relation to the Life of Plants and Animals." By Prof. L. C. Miall, F.L.S.

SATURDAY, March 5th.

INSTITUTION OF CIVIL ENGINEERS.

3 p.m. Students' Visit to the Oil-Gas Works of the Great Northern Railway, at Holloway.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture : "Matter at Rest and in Motion." By Lord Rayleigh, F.R.S.

The Electrician.

Published every Friday, Price Fourpence; Post Free, Fourpence Halfpenny
Editorial, Publishing, and Printing Offices:
SALISBURY COURT, FLEET ST., LONDON, E.C.
Telephone No. 2714. Telegrams: "ELECTRICIAN NEWSPAPER, LONDON."

All Letters relating to Subscriptions, Advertisements and other business matters should be addressed to the Publisher, "THE ELECTRICIAN," *Salisbury-court, Fleet-street, London, E.C. Cheques and Money Orders should be made payable to* "THE ELECTRICIAN" *Printing and Publishing Company, Limited, and be crossed* "Coutts and Co." *All Editorial letters to be addressed to the Editor.*

All letters intended for insertion in "THE ELECTRICIAN," *or containing questions, must be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever will be taken of anonymous communications.*

"THE ELECTRICIAN" *is published every Friday morning, in time for the morning mails.*

"THE ELECTRICIAN" *is on sale at the railway bookstalls throughout the Kingdom on Friday morning, and can be obtained of all Booksellers and Newsvendors; or direct from Publishing Offices as above.*

New Volumes of "THE ELECTRICIAN" *commence in May and November. Old Back Numbers and Volumes of* "THE ELECTRICIAN" *are frequently wanted, and offers will be made by the Publisher therefor.*

Subscription Rates.—The rates for Subscriptions to "THE ELECTRICIAN" are as follows:—

	3 months.	6 months.	12 months.
	s. d.	s. d.	s. d.
For the United Kingdom	5 0	10 0	19 6
For Foreign Parts and Colonies:—			
Within Postal Union	6 6	12 6	24 0
For Aden, Borneo, Ceylon, China, India, Japan, Java, Labuan, Mozambique, New Caledonia, Persia, Philippine Islands, Siam, Transvaal, and Zanzibar	7 6	14 6	28 0

TO ADVERTISERS.

"THE ELECTRICIAN" *offers exceptional advantages to Advertisers.* **It has by far the largest circulation of any English Electrical paper, and circulates all over the World.**

Advertisement Rates, &c., forwarded on application as above.

TRADE ADVERTISEMENTS *intended for the current issue must reach the Offices not later than First Post on Thursday. Renewals of expiring advertisement orders and alterations to standing advertisements must be in Publisher's hands by Wednesday at latest. No alteration can be made in Wrapper advertisements after Wednesday.*

SMALL ADVERTISEMENTS *accepted up to 4 p.m. Thursday.*

NOW READY.

TELEPHONE REFORM.

About the telephonic service in London it is impossible to have two opinions. No one has yet had the courage to defend it. Excuses and promises are the only replies which grumblings, protests, and, shall we say, imprecations have called forth. If GRAHAM BELL were held responsible for the profanity, and Colonel JACKSON for the loss of temper, that the telephone has caused, their burdens would indeed be serious. Improvement has doubtless been made of late, but the result is only to make communication possible where before it was out of the question, and to improve certain suburban districts where alterations could without serious difficulty be made.

At the crowded meeting at the London Chamber of Commerce on Monday last, although most of the speakers were more or less interested in telephone companies which compete with or intend to compete with the National Telephone Company, little blame was attached to the management, and the dissatisfaction and strongly-expressed complaints showed none of that bitterness which is justly felt at the meetings of the shareholders of ill-managed businesses. The original telephone companies came in for well-deserved reproach for the reckless mismanagement and scamped work which will never be properly punished. When every hard word has been said about the service, plenty more remain for the tariff. It is really only on this point that opinions conflict. It is pleaded that the tariff in provincial towns has been largely reduced; this is of course due to potential competition, and the cry at once is, let us have actual competition in London. Some ill-informed apologist thinks that because London is so vast special difficulties arise in the working of the exchanges; but we have only to look to Berlin or Paris and find 17,000 or 10,000 subscribers, as against the 7,000 of the London district. The 80s. per subscriber which

Digitized by Google

is spent on wayleaves is a significant sum, and certainly stands for some consideration received, which is more than can be said for the practically obstructive tax of £2 per subscriber which is exacted by the Post Office. But we will not dwell on excuses and complaints—a fair number of these will be found in our report of the meeting in another column. The real cause of the high tariff has been pointed out again and again, viz., the patching-up of the bungling work of the United Telephone Company, and the extravagant expenditure of paper capital on patents. Few monopolists have been better hated than the old United Company, and now that the patents have expired it is felt that their successors, the National Company, possess nothing but a good business—it would indeed be a misnomer to call it "goodwill," and the problem of to-day is how to get an efficient service at a reasonable cost.

On this main question hardly two speakers on Monday were agreed, this chiefly because most of them had axes to grind. The spread of State socialism so far affected the matter that there was an almost unanimous feeling, entirely unanimous if the voting for the resolution be considered, that "the Government ought to do something;" though this wish has been expressed, we believe, even before the Fabian Society sprang, or (is it more accurate to say) struggled, into existence. There was a distinct difference of opinion as to the exact course which it would be best that the Government should adopt. That a meeting of sixty men should hope to move the Government when it has a Bill of its own before Parliament is significant of the British spirit. By far the most reasonable suggestion was, that the Bills of the Telephone Companies should be allowed to go to Committee in order that public opinion should have a fair hearing. Colonel Jackson has a firm conviction that if he can only get compulsory wayleaves under, over and through public, private and other property, nearly all his troubles will vanish, and the troubles of the public are his troubles, for the grievances of the subscribers to his Company are not to be compared with the complaints of passengers on the South-Eastern Railway. Compulsory powers may be given or taken in Berlin; but they will be neither granted nor tolerated in this country. The New Telephone Company, which seems to mean business, asks for permissive powers only, though it remains to be seen how these will be interpreted. We are not convinced by the argument that general compulsory powers are impossible because electric supply companies only have powers over a district by Provisional Orders under the Electric Lighting Acts. There is no apparent reason, as far as that contention goes, why a similar Act should not be passed for telephones. But there is another and much more serious difficulty. We have never stopped to read the Magna Charta when we have passed it in the British Museum, and do not know if it contains a clause which constitutes every Englishman's house as his castle; but that right over his own property will not be given up until the present order of things gives place to Communism. The Post Office is more frequently thwarted by refusals of wayleave than is generally imagined, but the Post Office itself has never, so far as we are aware, attempted to take compulsory powers over private grounds and houses.

Very different views about the Post Office were held by different speakers on Monday. A good case was made out by those who showed that the Post Office had tried to establish telephone service in several towns, and had been beaten in nearly every case as soon as competition, even with single-wire circuits, began. But in view of the possibility that the whole matter may some day fall into its hands, it is well that the department should make a few experiments. It was confessed that trunk lines could be erected between towns, and maintained more efficiently and economically by the Post Office than by private companies; but there was a strong opinion that the Post Office could not be trusted to carry out the service with promptness, cheapness, and efficiency, that red tape and circumlocution would delay repairs to instruments and subscribers' lines, and that the determined obstruction which has already been offered, and the competition with the telegraph which would probably be felt, would make Post Office administration of very doubtful value. It is improbable that any guarantee could be obtained that the Post Office would not make the telephone a mere source of revenue. The advances of socialism have not been such that no voice was raised in favour of private enterprise; on the contrary, State management of commercial matters was discountenanced. But while the day is happily far distant when the Government baker will leave his rolls in the morning, and the Government milkman his milk cans (unless perhaps a pipe line will be laid from dairy to house), there is a distinct difference between a commercial supply and a public service. A Government department ought to be able to carry on a service, and if a monopoly must exist it is, on the whole, better that it should be in Government hands. As far as the London telephones are concerned, there is only one way out of the monopoly difficulty. At present it is essential to a useful service that every subscriber shall be able to communicate with any other. Where considerable competition exists, as at Newcastle, a large number of subscribers pay two subscriptions—the one to the Post Office, attracted, we understand, by good lines and instruments, and the other to the National Telephone Company because of its connections to other towns. Competition on these terms is ridiculous. We would prefer, then, to see the whole system put in the hands of the Post Office, unless an Act can be passed compelling competing companies to put through their own subscribers to those of other companies, precisely as the running powers of railway companies are arranged, the subscriptions to be settled on the Clearing House principle. Colonel Jackson is not altogether averse to being bought up by the State, but we fancy that if such an arrangement with the New Telephone Company were insisted on, and if his longed-for rights to plant poles in a bee line on any roof that was suitable were refused, he would have even less aversion to such a course than he has at present.

Loud and well-deserved as the complaints against the present service may be, the telephone is indispensable in thousands of offices, and with but one reserve we should like to see every endeavour made to facilitate improvements in it. That reserve is that the telephone companies shall not confine or curb the rights and operations of the rest of the electrical industry. To anyone who has heard of the contention of the telephone companies that they have an established right to use the earth as a return, and of their endeavour to stop electric traction and to divert the mains of, and otherwise harass, electric supply companies, it is very surprising that not a single representative of these threatened interests put in an appearance on Monday last. Where were the members of the Electrical Trades' Section of the Chamber? They had all received notice of the meeting. If they were too busy to attend, being for the most part engaged in manufacture, where were the Associated Statutory Supply Companies? The deputation to the Postmaster-General was nominated, and the Supply Companies have only themselves to blame if they are not represented on it, and though this may be no great matter, they will have reason for regret if the Telephone Companies steal a march on them, and succeed in getting even a portion of the powers which they are asking in their Bills.

ON A DIFFERENTIAL ELECTROSTATIC METHOD OF MEASURING HIGH ELECTRICAL RESISTANCES.*

BY MAJOR CARDEW.

The following method has been found useful for determining the relative value in insulating quality of small samples of materials, the insulation resistance of short pieces of cable, and other very high resistances. The arrangement is also suitable for continuously indicating the position on any electrical circuit, worked at a high pressure, of the resultant fault or point of zero potential; and for measuring the insulation of the circuit while the pressure is on.

Connections.—The method consists in connecting the quadrants of an ordinary quadrant electrometer to the terminals of a source of fairly high E.M.F., while the aluminium vane or needle is connected to earth. The resistance to be determined is connected to one side of this arrangement, and a variable resistance of the same order of magnitude to the other side, the free ends of each being connected to earth.

The centre of the battery, or other source of E.M.F., is then earthed for a short time, bringing the needle to the zero reading, and, after the removal of this earth connection, the needle will travel to one side or the other, unless the resistance to the passage of electricity from each pole to earth is exactly equal, in which case the needle will remain permanently at zero.

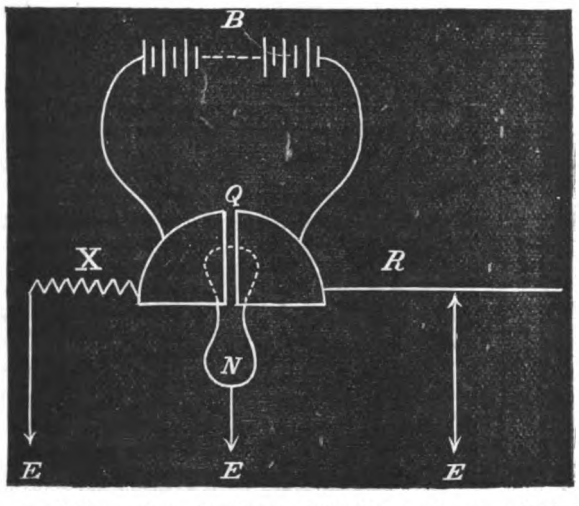

Diagram of Connections for Electrostatic Balance for Very High Resistances. The opposite quadrants of electrometer are not shown.

By observing the motion and varying the comparison resistance accordingly, this balance is soon arrived at, if within the range of variation provided.

The arrangement is shown in the figure, where B is the battery or other source of E.M.F., Q the quadrants, N the needle, X the unknown resistance, and R the variable resistance. The earth contacts are shown by E.

Principle.—The method depends upon the well-known fact that every source of electricity produces equal quantities of what are commonly called the two kinds of electricity in any time, however extended, and at any instant at an equal rate.

I have recently drawn attention to this law as determining the potentials from earth of the two sides of any system of electric supply (*vide* my Paper read on April 23, 1891, at the Institution of Electrical Engineers).

If we conceive, therefore, a perfectly insulated voltaic battery, the potentials of the terminals of this source from earth would be determined by momentarily connecting any one of the metal plates with the earth. Under such conditions, the smallest leakage from either pole to earth through a resistance amounting to many millions of megohms, if unbalanced by any leakage from the other pole, must rapidly reduce the potential of the imperfectly insulated pole to zero. The only limit, therefore, to the possibility of the method is the imperfection of the insulation of the measuring apparatus, and this insulation, with proper precautions, can be easily maintained at a value exceeding 1,000,000 megohms.

Sources of E.M.F.—A very convenient source of E.M.F. for the purpose is the arrangement of small zinc-copper couples in series, moistened by dipping the whole into a pan containing acidulated water, which is in use at the Physical Laboratory at Glasgow University. Four hundred such couples are usually arranged on an ebonite support, and the sensibility with this number is ample.*

A still better source, when alternating currents are available, is a special form of transformer, the secondary coil being suspended in air by a silk cord.

The highest insulation can thus be secured. But when the resistance to be balanced possesses appreciable capacity, the use of an alternating E.M.F. is unsuitable, on account of the masking of the effect of the leakage current proper by the capacity current.

Comparison Resistances.—The variable resistance is, most conveniently, some material of uniform cross section, so that its resistance varies as the length put in circuit. Reels of white silk, cotton, thread, and string are very suitable, and with a few such simple materials, balances can be obtained through a great range of value, although no multiplying or dividing power is possible. Thus, a white embroidery silk has been found to have a resistance of approximately 250,000 megohms per inch; a green thread, partly silk and partly cotton, 10,000 megohms per inch in a dry atmosphere; an ordinary measuring tape, 1,400 megohms per inch, &c., down to a piece of wet tape, which gave 64,000 ohms per inch.

These resistances are, to some extent, affected by the degree of humidity of the air, but, when necessary, they can be rapidly standardised with sufficient accuracy by determining one of the lowest by the usual method; or, as a check, when time allows, a highly insulated condenser can be shunted by a length of silk, and the loss of charge, in a given time, measured.

Unsymmetrical Insulation of Apparatus.—If, from any cause which cannot be discovered or removed, the insulation resistance of the apparatus is unsymmetrical, indicated by the needle taking up a false zero when connection is made between the battery and quadrants, symmetry can be always secured by connecting a length of silk, found by trial, between the more highly insulated pole and earth.

Limits of Accuracy.—The accuracy attainable by this method depends on the sensibility of the electrometer and the potential difference employed.

With an ordinary suspension, however, it has been found that with a battery giving about 350 volts, the difference in reading between that with the centre of the battery earthed and that with the earth connection made at 1 volt from the centre amounted to 12 scale divisions.

This sensibility should, therefore, be ample to secure an accuracy within 1 per cent., which, for resistances of several thousand megohms, is generally sufficient.

Leakage Indicator.—The same principle of balance may be usefully adapted as a leakage indicator for electric supply circuits worked at high pressure. For this purpose a special pattern of electrometer is requisite.

The quadrants are connected, respectively, to the two mains constituting a circuit, and the needle to earth. If the insulation of the entire circuit is good, the potential from earth of the two mains will probably be nearly equal, and the needle will remain at zero; any leakage taking place will disturb the balance to one side or the other. By temporarily switching a small leak first on one side and then on the other, and noting the effect, the absolute value of the insulation may be approximately assessed.

The arrangement is not applicable, however, to a concentric system of mains with alternating currents, or in any case where the capacities are large and seriously unequal.

* Paper read before the Royal Society, January 21, 1892.

* The mahogany legs supplied with this battery should be replaced by grooved ebonite legs, to improve insulation, and it is also of advantage to insert under each leg a piece of sealing-wax. The couples require to be taken out and cleaned occasionally; if allowed to get dirty, the E.M.F. becomes low.

THE TELEPHONE BILLS.

[COMMUNICATED.]

Bills have been introduced into Parliament during the recent Session by the National Telephone Company and by the New Telephone Company, with the object of obtaining statutory powers giving them additional facilities for conducting the business of telephonic communication. The powers sought by the National Telephone Company's Bill are of vast and far-reaching importance, and do not so far seem to have attracted the attention which they deserve.

After defining that the term "pipe" shall include "any pipe, tube, wire, or other apparatus laid in or under the ground for the supply of gas, water, electricity, or for any other purpose," the Bill proceeds as follows:—

"(1.) They may place and maintain a telephone wire under the public road, and may alter and remove the same.

"(2.) They may place and maintain a telephone wire over any public road, and may place and maintain posts on any public road, and may alter or remove the same.

"(3.) They may for the purposes aforesaid open or break up any public road and alter the position thereunder of any pipe, and do any other necessary act.

"(4.) They may place and maintain a telephone wire over any land or any estuary or branch of the sea, and may attach a telephone wire to any land and may place and maintain posts on any land, and may alter or remove the same."

It provides by Section 4 that the Company, in the exercise of such powers, shall do as little damage "as may be," and pay such compensation as shall be determined in manner provided by the Lands Clauses Acts, in connection with lands taken or injuriously affected. It provides by Section 5 that in altering the position of any pipe the Company "shall cause" as little detriment or inconvenience as circumstances admit, shall give at least 48 hours' notice before commencing works, and shall execute the work under the superintendence of the owners of the pipe. Clause 6 provides that the Company shall not place any telephone wire *under* any public road in London or towns having 30,000 inhabitants or upwards, without the consent of the road authority. Clause 13 provides that the Company shall not carry any telephone wire over any land not being a public road at a less height than 25ft., nor within 6ft. of the roof of any building, except with the consent of the owner or occupier.

The short effect of these powers is:—(1) To give the Telephone Company absolute right to place wires *under or over any private property without any consent*, and to leave the owner to take proceedings to determine the amount of the compensation to be paid to him. (2) To give the Telephone Company the right to place telephone wires OVER *any public road without the consent of anyone*, and under any road in the larger towns with the consent of the local authority; and, in smaller towns, without such consent. (3) To authorise the Telephone Company to *alter the position of any electrical pipes, tubes, wire, or other apparatus without the consent of anyone.*

Heretofore the Telephone Company have mainly carried on their business by means of overhead wires, which have been erected in pursuance of wayleaves obtained from the owners of property, and the business has been carried on as a private enterprise for the benefit of the shareholders.

We do not propose to discuss here the question of the effectiveness or cost of the telephone service; our only object is to call the attention of the electrical industry as a whole to the powers now sought. We are fully aware that so long as the Telephone Company confine their operations to those of a private undertaking, they are perfectly justified in carrying on the business in the manner that they might deem most beneficial to themselves. But when they go to Parliament and ask for compulsory powers to enable them to interfere with the rights of private individuals, it becomes a question of great importance how far such powers shall be granted to them, and to see that the rights of private individuals are not interfered with against their will, except so far as may be absolutely necessary in the interests of the public at large, and subject also to such reasonable regulations as may be desirable.

The deliberations of the Chamber of Commerce resulted in the passing of a resolution that the Government should be urged to bring in a Telephone Bill similar to the Electric Lighting Acts of 1882 and 1888, enabling the Board of Trade or other authority to grant powers to companies seeking statutory authority for carying on the business of telephonic communication. Such a Bill will, no doubt, provide regulations for the protection of the rights of the public and other undertakers, and determine the lines upon which the undertaking may be purchased by the Government or other authority at the end of a specified period or periods.

A few words now upon the proposed powers for altering the position of other electrical works without the consent of the owners. To say nothing of the difference in size and importance between the mains of Electric Light Companies as compared with those of the Telephone Company, it must not be forgotten that electric light mains can only be laid with the consent of the local authority, and subject to such regulations as they shall lay down, and in accordance with plans to be approved by the local authority, or settled by arbitration in case of difference. And it would lead, not only to enormous difficulty, but to great interruption in the supply of light to the public if it did not have the effect of altogether preventing the due conduct by Electric Lighting Companies of their business were these mains to be interfered with at the will of the Telephone Company. The telephone service, notwithstanding its defects, is undoubtedly of considerable value to the community; but, whilst one may have every wish to see the service made perfect, one cannot overlook the fact that it is possible to pay too large a price even for that perfection. The New Telephone Company do not ask for compulsory powers, save with the consent of local authorities or where they are affected by undertakers under provisional orders. They propose to lay down twin wires and to have no earth connections; and the rights asked by them may possibly be granted without detriment to any one, subject to the general questions which have been referred to above.

SOME EXPERIMENTAL INVESTIGATIONS OF ALTERNATE CURRENTS.*

BY ALEXANDER SIEMENS, MEMBER.

Most of the papers read before this Institution on the subject of alternate electric currents, and on apparatus employed for utilising them, have dealt principally with the theoretical side of the question, and undoubtedly have been extremely useful to constructors of alternate-current apparatus. Nevertheless, certain gaps in our knowledge obtruded themselves in practice, and the investigations and experiments which are described in the present communication were undertaken, not so much to verify any particular theory, as to increase our knowledge of useful facts. For convenience of reference, these experiments are not described in chronological order, but they have been grouped together according to the subjects which they are intended to elucidate. Foremost among these is the loss of energy through the heating of iron by induction where alternate electric currents are employed—a subject which engaged the attention of Prof. Ewing and of Dr. J. Hopkinson six years ago, whose researches pointed out the direction in which further experiments should be made. It is well known that this loss is caused by the so-called Foucault currents and by hysteresis. The effect of the former is counteracted by laminating the core of a magnet either by building it up with wires of small diameter or with thin discs, according to the direction of the lines of induction.

A short consideration will show that the heat produced by Foucault currents can be calculated beforehand for a core of known construction and dimensions. Take the case of an iron wire, 1 cm. long, subjected to an induction parallel to its axis of **B** lines per 1 square cm. of its section.

Let r be the radius of the wire, and ρ the radius of the ring, of the width $d\rho$, concentric with the wire. In this ring currents will be produced in the same manner as in the secondary circuit of a transformer.

* Paper read Thursday, 11th February, 1892, before the Institution of Electrical Engineers.

Digitized by Google

The maximum induction passing through this ring is $N=\rho^2\pi\,.\,B$. Hence the E.M.F. generated is $E=4\,n\,N\times10^{-8}=4\,n\,\rho^2\,\pi\,B\,10^{-8}$ volts.

If c is the conductivity of the iron employed, the resistance of the ring is $R=1/c\times2\,\pi\,\rho/d\,\rho$; consequently the waste of energy in this ring, expressed in watts, is

$$d\,W=E^2/R=8\,c\,\pi\,n^2\,B^2\,\rho^3\,d\,\rho\,.\,10^{-16}.$$

The total energy wasted in one cm. length of the wire is therefore

$$W=2\,c\,.\,\pi\,.\,n^2\,.\,B^2\,.\,r^4\,.\,10^{-16}\text{ watts.}$$

From this formula a table has been calculated to indicate the waste of energy by Foucault currents in 1 cwt. of iron of the conductivity $c=0{\cdot}102\times10^6$, when an alternate current of the frequency $n=100\sim$ per second was employed.

Induction.	½ mm.	Diameter of Wire. 1 mm.	Diameter of Wire. 2 mm.	3 mm.
B.	watts.	watts.	watts.	watts.
1,000	0·8	3·3	13·3	29·9
2,000	3·3	13·3	53·3	119·9
3,000	7·4	29·9	119·9	269·8
4,000	13·4	53·3	213·3	479·8
5,000	20·8	83·3	333·2	749·7
6,000	29·9	119·9	479·8	1,079·4

In order to determine the total loss of energy caused by the heating of the iron, experiments were made with a specially constructed "cable transformer." This mode of constructing transformers has been foreshadowed by Dr. Werner von Siemens, who proposed in his patent No. 42 of 1886 to surround the primary and secondary circuits of a transformer with iron wire, but his experiments gave no satisfactory results. The subject was recently taken up again, and the present form of these transformers was suggested by Mr. Dieselhorst and Dr. Baur. The principal advantage which is claimed for this form of transformer is that it can be made by machinery, in the same way as a submarine cable is made, the employment of manual labour in putting it together being entirely avoided. A special machine has been designed and erected for completing such transformers in one operation, after the iron core has been prepared on an ordinary rope stranding machine. Besides offering these facilities for manufacture, the peculiar shape of the cable transformer lends itself to a variety of useful applications. For instance, at the Crystal Palace Exhibition one of these transformers connects an alternate-current machine to a high-voltage transformer some distance away, raising the potential of the current at the same time from 80 volts to 2,500 volts.

The transformer used for the experiments has a core of 900 soft iron wires, each 1mm. in diameter by 6 metres long, twisted up in the form of a rope, and surrounded by two windings of copper wire, properly insulated, the one for high voltage and the other for low voltage.

From the fact that the diameter of the transformer is very small compared to its length, it follows that the magnetic field, and consequently the induction in the iron core, is uniformly distributed, with the exception of a slight drop at either end. The mean induction produced by passing an alternate current through the low-voltage circuit was measured by the difference of potential obtained in the high-voltage circuit while no current was passing through the latter.

The temperature of the iron core was ascertained by measuring the increase in the electrical resistance of one of its wires, which had been insulated from the rest by a cotton covering.

By actual comparison it was found that one of the wires near the periphery gave, within the limits of errors of observation, the same results as the central wire, so that the exact position of this "test wire" has no influence on the result; the heating of the cotton insulation can be neglected, as its mass is so very small compared with that of the iron.

Separate tests were made to determine the specific heat of the iron, which was found to be $=0{\cdot}112$, and the temperature coefficient for the electrical resistance of the test wire, which was equal to 0·0054.

The current was kept on for a short time only, as it was desired in the first instance to determine the rate at which energy is converted into heat in such a transformer, and the rise in temperature after keeping the current on for s seconds can be calculated from the formula,

$$t_s=\frac{R_s-R_0}{\cdot0054\,.\,R_0}.$$

R_0 = electrical resistance before starting the current; R_s = electrical resistance after keeping the current on for s seconds.

During the time that the current passes, the test-wire will lose a certain amount of heat by radiation and convection, although it is surrounded by all the other iron wires, which are heated in a similar manner. This loss can, however, easily be allowed for by plotting a "cooling curve" after the passage of the current has been stopped, with times as abscissæ and temperatures as ordinates. In this way the rise of temperature of the iron core per second was observed with an alternate current of 100 $\sim$ per second, varying in strength so as to produce a different induction for ach observation.

Considering that the loss of energy caused by the heating of the iron is proportionate to its mass, to its specific heat, and to its rise of temperature per second, it was possible to plot a curve in which the maximum number of C.G.S. lines per square cm. are the abscissæ, and the losses of energy are represented as ordinates calculated for the mass of 1cwt. of soft iron wires 1mm. in diameter.

It should be added that the abscissæ of curve 2, Diagram I., which embodies the results obtained, have been calculated from the measured volts, instead of from the calculated mean volts, which in sinoidal waves are $=0{\cdot}9$ measured volt. This was done as curve 2 was to be used for designing transformers where the measured volts only are used for calculation. As this curve gives the losses caused by hysteresis and by Foucault currents, while the formula given above enables us to calculate the losses caused by the Foucault currents alone, we can determine the loss by hysteresis alone by a simple subtraction.

All these results, it must be remembered, refer to 1cwt. of soft iron, subdivided into wires of 1mm. diameter, on which an alternate current is acting of a frequency of 100 $\sim$ per second, the type of apparatus used being a cable transformer.

The following table shows the results:—

Induction.	Curve 2.	Losses of energy. Foucault currents.	Hysteresis
B=	watts.	watts.	watts.
1,000	43·2	3 3	39·9
2,000	96·2	13·3	82·9
3,000	158·0	29·9	128·1
4,000	231 2	53 3	177·8
5,000	309·5	83 3	226·2
6,000	390·1	119·9	270·2

The losses caused by hysteresis are independent of the dimensions of the iron; this table enables us, therefore, together with the formula for the losses caused by Foucault currents, to predetermine the rate of the loss of energy in iron wire of any weight or dimensions when acted upon by an alternate current of a frequency equal to 100 $\sim$ per second.

Similar experiments were made with alternate currents of a frequency of 66·6 $\sim$ per second, and of a frequency of 133·3 $\sim$ per second, and the curves embodying the results are also shown on diagram I. It should be observed that the currents of 66·6 and of 100 $\sim$ were obtained from the same alternate-current machine (type W_1), which has a high self-induction in the armature, and of which it has been ascertained experimentally that the waves of its current are sinoidal. The currents of 133 $\sim$ per second were produced by another type of machine (W_{11}) with a low self-induction and a very narrow field.

On diagram II. the losses by hysteresis alone have been shown, derived from the curves of diagram I. by deducting the losses caused by Foucault currents according to calculation. By way of comparison, Professor Ewing's curve of losses caused by static hysteresis has been added. In this table the results obtained with alternate currents of 133·3 $\sim$ per second have been left out of consideration, on account of their being made with a different machine, as just explained.

The next point to be investigated is the change which an alteration of the frequency of the current will involve in the case of a transformer designed for a given voltage in its secondary circuit. If it is borne in mind that this voltage, apart from the constant factors, depends on the product $n\,N$ (n denoting the frequency, and N the maximum number of lines of induction), it follows at once that, in order to produce the same E.M.F. with a lower frequency, the number of lines of induction has to be increased in proportion, and *vice versa*. In other words, if the same E.M.F. is to be produced in the secondary circuit of a given transformer, the product $n\,N$ must be constant. This result can at once be applied to the formula, which gives the losses of energy caused by Foucault currents—

$$W=2\,c\,\pi\,n^2\,B^2\,r^4\,10^{-16};$$

and as $N=r^2\,.\,\pi\,.\,B$, the formula can be expressed—

$$W=\frac{2\,c}{\pi}(n\,N)^2\,10^{-16};$$

or, in other words, these losses are constant for the same trans-

Digitized by Google

former, whatever the frequency may be, as long as the E.M.F. of the secondary circuit remains the same.

A comparison of the curves for a frequency of 66·7 and of 100 ∿ per second on Diagram I. shows that the losses of energy for the same induction are practically proportional to the frequencies. The same curves show that this loss increases more rapidly than the number of lines of induction.

weights of the iron and of the copper used in its construction are equal to each other and to 1 cwt.; this may be called the normal transformer. If, now, another transformer, of the same series but with a lower induction, is to produce the same voltage, the section of the iron has to be increased proportionately; for instance, in the case of B = 2,500 it has to be doubled. The weight of the iron employed varies, in fact, inversely as the induction, and their

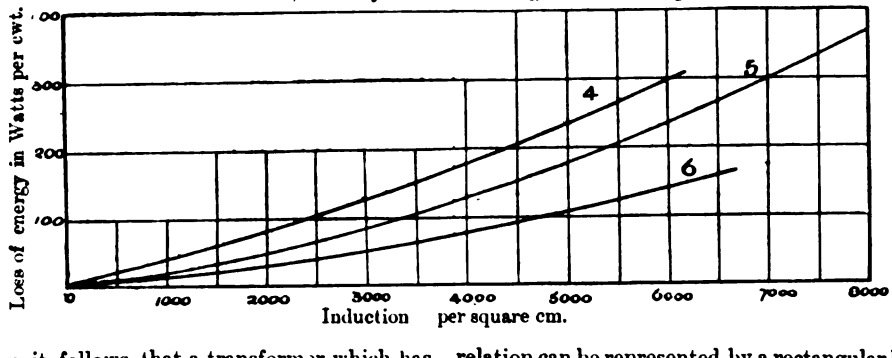
DIAGRAM II.

Loss by Hysteresis only—Curve 4, frequency = 100 ∿ per second; curve 5, frequency = 66·7 ∿ per second; curve 6, static hysteresis according to Prof. Ewing.



From this consideration it follows that a transformer which has been designed to produce a certain E.M.F. in its secondary circuit with a given frequency cannot produce the same E.M.F. with a lower frequency without over-heating, while it remains cooler when it is worked with a higher frequency. In other words, transformers built for low frequency require much material.

An experiment was made to ascertain the final temperatures of a 50-H.P. transformer worked with different frequencies, and after 10 hours' working the maximum temperature was found to be—For a frequency of 100 ∿ per second, 53°C. in the core, and 46°C. on the outside; for a frequency of 66 ∿ per second, 69°C. in the core, and 57°C. on the outside—a result which appears to bear out the above consideration.

What frequency is most advantageous can, however, not be settled by taking into account nothing but the heating of the transformers: it is quite evident that the construction of suitable generating apparatus plays as important a part; and the problem resolves itself into the commercial one: which combination of apparatus can be constructed most cheaply?

The question, what induction should be settled upon in designing a transformer, is rather a complex one, and it can only be solved by taking into consideration—

1st. The amount of material, iron and copper.

2nd. The drop of potential difference in the secondary circuit from no load to full load.

3rd. The efficiency of the apparatus.

4th. The heating of the apparatus.

In order to facilitate the investigations a series of transformers is compared which all have the same length of iron core, and the same number of turns of copper wire of the same diameter. It is assumed that one of these transformers is designed for an induction B = 5,000, and that its output is such that the relation can be represented by a rectangular hyperbola (Diagram III., curve 7). As we have assumed that the thickness of the copper

DIAGRAM III.

Induction B per square cm. Section.

wire and the number of its turns are to be the same in all these transformers, the weight of the copper will vary directly with the

Digitized by Google

length of wire wound on the iron core, and this can be determined if the relationship between the length of periphery and the section of the iron core is known. In the case of the sections of the cores being circles or squares or rectangles, with the same ratio between their length and width, the length of the periphery varies as the square root of the section. As transformers are generally designed with cores of this kind, it may be accepted that the periphery of the iron core, and, consequently, the weight of copper to be employed, varies as the square root of the section of the iron core.

The weight of copper in the series of transformers under contemplation can therefore be represented by a curve (Diagram III., No. 8) the ordinates of which are the square root of the ordinates of the curve giving the weight of iron for the corresponding inductions. From these two curves it appears that the weight of the iron increases very rapidly with decreasing induction, while the weight of copper increases at a slower rate.

As materials are important items in the cost of a transformer, the consideration of the first point shows the desirability of employing a strong induction. A similar conclusion will be drawn from the investigation of the relation between the induction and the drop of difference of potential in the secondary circuit of the series of transformers. As they are all supposed to give the same current, the drop from no load to full load will be in proportion to the resistance of the circuit. This resistance is in proportion to the weight of copper employed, as all the transformers are assumed to be wound with wire of the same diameter. The curve (8) giving the weight of copper at different inductions will therefore also indicate, in comparison with the normal transformer, the variation in the drop of potential between no load and full load under the same circumstances.

(To be continued.)

THE LONDON TELEPHONE SERVICE.

A special general meeting of the London Chamber of Commerce was held on Monday in the Council Room, Botolph House, Eastcheap, Sir Albert K. Rollit, M.P., presiding, "to consider the general position of the commercial community in regard to the Telephone Service of London and the Telephone Bills now before Parliament." There was a large attendance.

The CHAIRMAN, after stating the object for which the meeting had been convened, said he thought he need not say, as Chairman of the Council, that the feeling of the Council on the subject which they had met to consider was probably the feeling of every member of the Chamber, namely, that the question was not only one of the most important that could be brought before the Chamber, but that its importance was increasing day by day. Owing to the competition which our merchants and others had to meet in the markets of the world, despatch was daily becoming more and more an element of business, and they felt that the saving of time was the only means of making a profit. For these reasons it became of very great importance to consider whether their methods of communication, of transport, and the like, were in the most efficient condition ; and that the public mind was directed very much to these questions was shown by the interest which was taken in the Railway Bills when they were before Parliament, and by the interest which was now beginning to be shown in the Telephone Bills which Parliament had to consider this Session. The Chamber had long taken an interest in these matters. It had appointed one, if not more, committees for considering it, and as some differences of opinion had existed on these committees, it had been thought desirable that the whole of the members should be called together to consider the subject. He thought that perhaps one of the first questions they would have to deal with would be whether, considering the importance of communications as an element of commerce, the fullest and best development had been given to the telephone system in this country under existing conditions, and whether other nations were enjoying greater advantages and greater cheapness from the system than we were. For his own part, although he intended to forbear from expressing any strong opinion, and although his mind, as Chairman, would be kept open for what he might hear, he could not help thinking, from the experience he had had of various telephone systems in foreign capitals, that there was greater development of the system there than there was in this country, that it was cheaper, and, on the whole, more effective, he thought. He could not also conceal from himself the fact that in America the long trunk lines were more generally used than in our country, although here we were in nearly the same position as they were across the Atlantic as regarded the circumstances surrounding the use of trunk lines. On the opening of the telephone system between Paris and Marseilles, no communication could have been easier and better. If it were the fact that they were not quite as much in advance as other countries in regard to the telephone system, they must seriously bethink themselves, for if there was one cause of our present commercial position it was because, in relation to steam and such matters, we had been in advance of all other nations ; and everyone must feel, viewing the importance of the telephone, that we ought to be, at any rate, equal in this country to other nations in this application of electricity. Then came the question as to whether the cost of the telephone in this country was as cheap as it might be, having regard to the experience of other nations. As far as his experience went, he certainly ventured to think that there was room for a reduction in the cost here. The most important question of all, probably, was whether the system in this country was as effective as it might be. He had for many years past taken a scientific interest in electrical questions, telegraphic and telephonic. He possessed the second pair of telephones, apart from any microphones, which were brought to this country, and which were given to him by his friend Prof. Graham Bell. What had struck him had been that the difficulty in regard to telephony had been the cardinal one of induction. As far as he was able to judge, he did not think that this difficulty would be overcome until there was a more general use of a second or return wire. He believed this to be a necessary element of efficiency in the telephone. It might, and probably would, add to the cost, but still, the cost of material was being greatly reduced, and efficiency, after all, was the great consideration. Then there was the element of the mode in which the service was conducted—he meant through its staff—not the superior departments, but those who administered the wires and messages, and on this point his experience was that the service was bad. He was, however, bound in fairness to add that this had been altered and considerably improved. He did not know whether there might not be further improvement. With reference to the Bills in Parliament, as they were aware, whenever a complaint had been made the allegation had been that owing to the absence of powers the telephone companies had been unable to give proper efficiency. In connection with this point they would have to consider, whether, before powers were given to the companies, the assurances they gave were satisfactory that they would consider the public interest first, or, at any rate, equally with the dividend to their shareholders. They had the general principle to bear in mind whether it was desirable that compulsory powers should be given to any private trading company, and, lastly, they had to fall back on the question whether this was not a matter which ought to be conducted by a State department. For his own part, speaking generally, he must say that one's experience of similar things in the past—not of the same undertakings—had led one to the conclusion that wherever the Government could be trusted to provide public facilities better and cheaper than individuals could supply them themselves, there was a manifest advantage in this public supply. There was a manifest disadvantage in the growth of vested interests (as in the case of the water supply), which ultimately had to be bought out at a very serious cost to the community ; and if one could really believe that the telephone, like the telegraph system, could be conducted in a manner thoroughly efficient, and if they could be satisfied that it would not be the case, as in the Post Office, that too much of the receipts were devoted to revenue purposes instead of being applied to the increase of commercial facilities, which was all-important, then he thought there would be a strong inducement to believe that the State ought to do its duty in this matter, and that the efficient performance of this duty should be insisted upon and required from Parliament by the community. He thought there was a further consideration which ought not to be lost sight of, namely, that this matter was important, not only directly, but also indirectly. Directly, it was important as an element of commerce in cheapening the cost of production, but indirectly, electrical engineering was a branch of science to the scope of which in these days there appeared to be no limit. Many industries were dependent on it. A branch of industry which employed almost countless numbers of people was one which should be managed in the most progressive way in this country. He mentioned this last reason as an additional one to those which he had already indicated. They might say that this great branch of trade—electricity—underlied all other trades. It was, therefore of vital importance to the community that every possible advance should be made, that the public mind should be kept educated on all points, and that the public should have the advantage given to it of all progressive improvements. To a great extent this would be done through the general and technical education which so many were now advocating ; but it must be borne in mind that practical education in the shops was of the first importance. This country had placed itself at the very head of mechanical arts, and it ought to be in the forefront in this matter. They must insist that the best and the most recent facilities should be given to the public in supplying their commercial wants, this being of vital importance to the country ; and that was the spirit in which he hoped this important subject would be discussed that day.

Mr. F. W. REYNOLDS said that as the Chairman had appealed to some member of the Chamber in connection with the moving of a resolution, it would, perhaps facilitate matters if he himself did so. At the present moment, as they were all aware, they were severely handicapped in nearly all the markets of the world, and they had only just had to submit to further imposts on the part of the French Government. The American markets were closed to them, or nearly so, and therefore it was a matter of the greatest importance to them to get quick answers to their enquiries. He had had several cases of foreign merchants being in this country and wanting certain orders executed, and it had not been a question of price with them, so much as the rapidity with which the work could be done. He was not afraid, nor were British manufacturers and merchants, of any competition, but they certainly looked to their getting every facility given to them so that they might not be more handicapped than they were already. He thought they should approach the Government, and ask them to give such facilities, or do the work themselves, as would ensure the best means of communication being provided. He had a private wire, and he was bound to say that it worked pretty well, and when it got out of order the telephone employes came and put it right. He heard, however, complaints from other people, and in his own case he found it was difficult to get on at the exchanges. He proposed the following resolution :—

"That in view of the importance of the telephone industry, and the fact that two separate Companies have Bills before Parliament, this Chamber should appoint a deputation to apply for an interview with the Postmaster-General and express the views of the Chamber as to the extreme importance of Her Majesty's Government bringing a Bill before Parliament in order to

Digitized by Google

dealt with the question of providing means for giving perfect facilities for the development of this enterprise, not only in the Metropolis, but also with regard to inter-town service all over the country."

Mr. J. MARTIN seconded the motion.

Mr. JACKSON enquired the scope of the Bills before Parliament of the two companies.

The CHAIRMAN read the marginal notes of the National Company's Bill and subsequently clauses 36 and 37 of the Bill of the New Telephone Company. He afterwards observed that the powers in the latter Company's Bill appeared to be somewhat more permissive than contractual, as in the case of the National Company's Bill. It was, however, open to those connected with the companies to construe their own Bills.

Mr. J. CHAMBERS said he failed to see the object of applying to the Postmaster-General. The Telephone Committee with which he (the speaker) had been connected for some time had heard both sides of the question, and had had representatives of both companies present at their conferences. He might be thought presumptious in crossing swords with the Chairman, but he would move, as an amendment to the resolution, the resolution which the Telephone Committee proposed, and which was to be put before the Council. It was as follows:—

"That we are of opinion that an efficient telephone service cannot be given to the Metropolis unless statutory powers are conferred on the companies, and the Council of the Chamber are requested to take the necessary steps to give effect to this recommendation."

He failed to see that there could be any monopoly in this matter. They had two large companies, who were urging their claims before the public, and he thought that the public were better served by these companies than they would be by the Post Office. When the National Company went to Birmingham, the Post Office telephone lost—he did not know how many exactly, but a considerable number of their subscribers, who joined the National Company. There had been complaints, but how had they arisen? It was because there were no statutory powers, and sometimes, where it was a case of going only three miles, the Company had to go six miles in order to get at the point they desired to reach. If these companies were ready to serve them, and could get the necessary statutory powers, so that they could efficiently carry out the telephone service in the metropolis, they ought, as commercial men, to strive to secure for them those powers by all the influence they possessed. He did not see where the Post Office came in; and he did not like concentrating everything. He would rather depend on competition, and, of course, the public would go to the company which served them best. He did not like approaching the Postmaster-General, but although he was proposing an amendment, he believed he was quite in accord with the mover of the resolution.

Mr. FAITHFULL BEGG seconded the amendment, observing that everything which had fallen from the previous speaker was in agreement with his own ideas of the question before the meeting. The subject of the development of the telephone resolved itself into the question referred to by the Chairman in his opening remarks—namely, was it to be done by the Post Office or by private enterprise? He quite believed that the time would come when it would be necessary that the Post Office should control the telephone in this country, but if they were to judge by the past, they had no guarantee whatever that the work would be undertaken in any reasonable period if it were left to a public department. The evidence of that was in the fact that when this enterprise began to be opened up, the Post Office intimated publicly to the country that it was willing to undertake the duty, and to establish telephonic exchanges wherever they were called upon to do so; but notwithstanding that, the Post Office was left to-day without any telephone exchange of any importance.—(A voice: "Newcastle.")—He excepted Newcastle, but he did not admit that Newcastle was a telephone exchange of any importance. He maintained that the Post Office was left without any telephone exchange of any importance, and had been beaten by private enterprise out of several towns where it had established some sort of footing. He believed that this was through the genius of the department not being able to deal with this question as it could be dealt with by private enterprise. As to the metropolis, it was well known that the difficulties were such as did not exist in any part of the civilised globe—they were enormous. The number of subscribers to be put into communication was very large, and it was necessary in London, if it was necessary anywhere, that there should be statutory powers. He did not urge that anything exceptional should be granted. The powers to which he had referred had been granted to other companies. They had granted to the Electric Light Companies the power of taking up the streets, and a nice mess they were making of them; but perhaps the result would justify this. They were now beginning to admit that the telephone was of some importance, and why should it not have the same facilities? This was all, he believed, that the mover of the resolution proposed. The Postmaster-General was an interested party. He had telephones of his own. He did not know what good they would get by going to any department. If they appealed at all let them appeal to the Government, and ask that the industry might be given the reasonable powers which were now advocated for its development.

The DUKE of MARLBOROUGH (New Telephone Company) stated that the subject was a very intricate one, and it was of enormous importance to the community at large. He would take the point raised in the second resolution before the Chamber, which Mr. Begg had particularly alluded to—that was, the question of the Postmaster-General in this matter. Let them consider for a moment what the telephone was. In a country the size of England they ought to be able to talk from one end of the country to the other easily. If they had a good system anyone ought to be able to talk with facility from that room to some one in Glasgow. By going to the Post Office they could talk with the greatest facility between London and Paris. It had been said that private enterprise ought to be developed, and that statutory powers ought to be given to the Companies by the Postmaster-General. This was a perfectly open ground for discussion, but he wanted to put before them this consideration. They were not only a Chamber of Commerce, but also members of the Empire from the point of view that they were all taxpayers. They had bought the telegraph at a very great cost, and they were losing money by it. Supposing the telephone developed in the hands of the present two Companies—or more—what would be the effect? The moment they had a perfect trunk system all over England the telegraph would be cut out, and the Government knew this. If the Government had bought up the gasworks they would not have had Bills passed sanctioning the electric light. As to whether they ought to approach the Postmaster-General, he submitted to the Council that the inter-town communications of this country should be in the hands of the Government. There was no Bill they could pass for any Company that would give sufficient powers to the Company to lay this system as the work should be done. The Government could lay systems as much as they liked under their Telegraph Bills; they could lay them economically and cheaply, and could give facilities which a private company could not give—he was speaking about inter-town communications. Their interest as the public could not be served, he maintained, unless the Government took up the inter-town part of the work. They would not get it good or cheap unless it were done by the Government; and they were bound as taxpayers to protect what they had bought—the telegraph. With respect to the Bills before Parliament, there was no doubt that the Post Office had behaved in a most obstructive manner in dealing with this question, and he sympathised very much with the United and the National Companies in not being able to get anything from the Government—in fact, those companies had met with perpetual opposition. He knew that the Postmaster-General was going to bring in a Bill of his own for the purpose of dealing with the telephone and for conducting it on the underground principle. He knew also that both the private Bills were to be opposed by the Postmaster-General. He thought it very unfortunate that the Government should oppose these Bills at the earliest stages. He considered that they ought to be allowed to pass their second reading and get into committee, so that people might come and give evidence for and against them. The public would then be able to judge of what should be done, and the matter would have light thrown on it. He thought it unfair that the Bills should be thrown out in their early stages, but no private Bill before Parliament had a chance if the Government were opposed to it. It was really absolutely necessary that the Chamber of Commerce should take some active line and represent its views to the Government. Otherwise the companies themselves were perfectly powerless to use any influence of their own to get their Bills carried. He thought that the first resolution was an important one. As to whether the Government could do the work of distribution, abroad the telephone was a monopoly in the hands of the Government, and according to the bureaucratic notions prevailing there, the plan suited foreigners. It would not, however, suit Englishmen. They did not want, when a wire was broken, to have to go through some circumlocution office, as abroad, to get anything done. The Government should be like a farmer who kept a lot of cows and sent his milk to London, employing others to deliver the milk. It would be found that the Companies would do the distribution part of the work better than the Government, but undoubtedly the Government would do the inter-trunk work better than a private company. He thought that this was one view of the situation he would like to put before the meeting. With regard to the question of compulsory powers, Parliament would never give statutory or compulsory powers to a private company. There had been several instances where this had been done, and the result had not been satisfactory. The Electric Lighting Companies were different. Provisional Orders were given to different areas, but they were all given under a general Act. They could not pass a general Act for dealing with the telephone. As a matter of fact, Parliament would never grant the principle which the National Company was applying for. They really, therefore, need not consider this question. It was really of no use bringing before Parliament the resolution which had been passed by the Telephone Committee of the Chamber of Commerce, as they would not adopt it and give to a private company the powers asked for. As regarded the question of the cost of the telephone, there was no doubt that the price paid by subscribers of £20 was too much. He did not wish to make any rash statement, but he maintainad that £12 was a proper price for the use of the telephone on the twin-wire system.—(A voice: "£8.")—They ought to be able for their £12 to speak all over London and the Provinces, paying an extra cost to the Government for the latter privilege. An efficient system by which one could hear plainly was of the greatest importance, for unless one could hear, the telephone was a most maddening instrument (laughter). If he were given the power of putting a few tubes under the pavement he would give them a telephone system immediately communicable, and with practically no wires overhead. It was perfectly possible to give a system by which they could get round to five or six people in a few minutes. An eminent patent lawyer, who was thoroughly up in all electrical science, said to him the other day, "Bad as the system is—and nothing could be more execrable—it is worth £1,200 a year to me in my professional business in what it saves." That was the case, and if they could all have in their offices and homes an efficient telephone they would save largely by it in money, time, and the journeys which at present they had to take, to say nothing of the letters which they had to write. He regarded the Bills before Parliament as attempts to bring the backers before public notice, but he urged them to agree to the first resolution as a very important one. With all deference to the gentleman who proposed the amendment, it was of no use going for a *non-possumus*.

Mr. CHAMBERS pointed out that his amendment did not specify that any special powers should be given.

Digitized by Google

The DUKE of MARLBOROUGH, continuing, repeated that he did not believe that Parliament would give the statutory powers demanded, either to one or to a dozen companies. On the other hand, it was most valuable that the Chamber should extract from the Government some expression of opinion. They were all very much in the dark, and the only means of finding out what was going to be done was for a Chamber such as theirs to approach the Government, and say to them, in so many words—"We want the development of this enterprise; we want to know whether Parliament is going to give statutory powers to a private company, or if Parliament does not approve of that, whether it will grant such facilities under a general enabling Act, which will allow this important industry to grow."

Colonel R. R. JACKSON (National Telephone Company) said he had listened with great interest to the lucid and compact form in which the Chairman had put before the meeting the questions that it would be called upon to discuss, and he trusted that he would be permitted to deal with a few of them. First of all, he desired to allude to the resolution and the amendment which were before the meeting. For his own part he was utterly indifferent whether the motion or the amendment was carried, because the purpose of both was practically the same—that was, to secure statutory powers under which the companies would be enabled to do their work by the instrumentality of a general Act. The National Company, although they did 83 per cent. of the telephone business of the country, and its sub-companies did 10 per cent. more, did not ask for special powers on behalf of itself. His belief was that such statutory powers as one company might possess ought to be accorded to all, and he thought that the resolution would lead to that conclusion. He thought also that the amendment would lead to the same conclusion, but he considered that the amendment put the matter much more pithily, because it asked simply that some general Act should be passed by Parliament, and that the resolution which had been come to by the Telephone Committee of the London Chamber of Commerce should be accepted by that meeting, and that it should be presented to the Government as indicating the view of the Chamber. He did not believe that a resolution of this kind, put before the Government, which had been passed by a body of men so influential as the merchants of the City of London, could meet with other than respectful attention. The Chairman had referred to the cost of the telephone, and so had the Duke of Marlborough, but neither gentleman was aware that, although the telephone was given to the public much cheaper in some countries than it was in this, it could be worked for much less in other countries than here. Last autumn he was in Germany, and he saw the telephone systems in Dresden and Berlin. Owing to the kind assistance of the British Ambassador, he was permitted to go through the Berlin Exchange system, and he had every information given to him in connection with it. There they had 17,000 subscribers, while in London there were only half this number; but why, could it be offered cheaper there than here? It was in the hands of the Government, and the Government had no wayleave difficulties. The Government planted five exchanges in such parts of Berlin as it thought would be the best, each capable of giving accommodation to 6,000 subscribers. It had about 3,500 subscribers on each, and the wires were run almost as the crow flies from exchange to exchange, and also from the exchanges to the subscriber's office or residence. There was no royalty to pay of 10 per cent., there were no wayleave charges, and where a mile of wire would do only a mile was run. He hardly ventured to tell them what they were paying in London for wayleaves, but it was over 30s. per subscriber; they paid to the Government £2 for royalty; and they often had to run a mile and a half or two miles of wire where one would do. They completed a route, and were then ordered to remove their standards from the top of a building, and, at great cost, they had to take a circuitous route to obtain complete connection. When Sir Albert Rollit and others suggested that there should be a reduction of the cost, he wished to tell them that this was consistent with the desire and principle of the National Telephone Company—that where possible the cost should be reduced. There was a very large reduction all through the Provinces the year before last, and that reduction had had results which encouraged their Company to prefer lower to a higher charge; but what was their experience in London? If they lowered the tariff now in the metropolis, and thus allured to their system a large number of people wanting to have telephonic facilities, they could not connect them up, and until some such resolution as that which had been proposed was passed and given effect to by Parliament, it would be a doubtful policy for the Company to lower its tariff in London, for it would cause disappointment all round. Let them have statutory powers enabling them to do their work as it ought to be done, and then the question of reducing the tariff could be dealt with in earnest. Something was also said about the inadequacy of the service given in London (hear, hear). That "hear, hear" corresponded with his own experience. He entirely concurred with the sentiment. When the National Company took over the system of the United Company, it was found that a general reconstruction was necessary. His Grace had said that the National Company had two exchanges; but instead of two they had 22, and their first effort was to connect these 22 exchanges with such a number of wires as would enable the subscribers on one exchange to talk with rapidity to the subscribers on another. As the distance between them was very great it resulted, as the Duke of Marlborough said a short time ago, in their converting all the connecting wires between the exchanges into metallic circuits. Sir Albert Rollit had very candidly acknowledged that the service had recently been improved. He desired to tell them what happened in the middle of January. After struggling for more than two years to get a sufficient number of wires erected between exchange and exchange, and to convert them into metallic circuits, they succeeded in the middle of January in running nearly an adequate number of these wires to a new switchboard especially constructed for the purpose at Cannon-street, the result being that the service had greatly improved. The Duke of Marlborough was quite mistaken when he thought that these efforts of theirs were all that the National Company intended to do. As regarded an area so large as that of London, with wires so long as many of them were, with an utter incapacity to carry the wires needed overhead—with, therefore, the necessity to run an enormous number of wires underground—they recognised that metallic circuits were indispensable for a perfect system; and, recognising that, nearly two years ago they applied to the Commissioners of Sewers to permit them to put pipes under ground. This would have enabled them to give the City, which contained two-thirds of their metropolitan subscribers, the advantage of a metallic circuit, and they further sought to concentrate the six City exchanges into one. Had the Commissioners of Sewers given them the power asked for, they would now have been a long way towards the development of the metallic loop system in the City; and as soon as they obtained the power which they sought they would take this work in hand. They were also looping or converting into metallic circuits the subscribers' wires in the suburbs. They had done Croydon and Sydenham, and they were taking the others in turn, as the men could get to work. They wished to do the same for Kensington, but they could not obtain the wayleaves. The public was under a grave misapprehension when it thought that the Company did not wish to give the benefit of the metallic circuit to London. The reason they had not given it was because they could not give it; but they did the best they could. A great deal had been said about the twin-wire and the single-wire system as a general factor in efficiency. He wished to point out that throughout Germany—even in Berlin, where, as he had said, they had 17,000 subscribers—they had the single-wire system entirely. In Austria they had the single-wire system everywhere except in Vienna, and the reason they had the double wire in that city was that the authorities insisted on the wires being taken underground. In France they had the single-wire system everywhere but in Paris, and there the construction of the sewers—the peculiar character of the sewers—necessitated the adoption of an underground, and therefore necessarily a metallic circuit service. In this country everywhere but in the Post Office exchanges, and in one exchange at Manchester, the single-wire system prevailed. They had been told that wherever a single-wire system and a metallic circuit system came into contact, the single-wire system must go to the wall. The Duke of Marlborough had touched upon that subject, and he would, therefore, tell them what had happened in Leicester. The Post Office had an exchange there of several years' standing, with 133 subscribers. In January, 1890, the National Company opened an exchange there; and while the Post Office had now 100 subscribers, the National Company had 275. In Hull they were invited by all the public bodies to open an exchange. They did so; and although the Post Office had been nursing its system for ten years, the National had now more subscribers. The single wire system was adapted to places where they could have one exchange, where the wires were not of great length, and where they had not to go underground. He thanked Mr. Chambers for his resolution, which was in harmony with what had been done by the telephone committee of the Chamber; and the gentlemen present for the patience with which they had listened to the statement made by himself; but before sitting down he felt bound to deal with one subject which had been mentioned by the Duke of Marlborough. His Grace had referred to trunk wires, which he said he thought ought to be in the hands of the Government. Now, the National Company had 30,000 miles of trunk wire; and various towns in the Provinces, in Lancashire, in the Midland district, in West Cumberland, and all through Scotland, were connected with each other. Ten million messages a year passed through those wires, and cost less than a penny each. Therefore, the National Company's trunk system, connecting town and town, was of very great importance to the community, and he thought that those who had tried it would say it was efficient. When the Duke of Marlborough said that it ought to be in the hands of the Government, he (the speaker), as connected with the National Company, said that it was of immense importance to them in enabling them to meet the competition which every man engaged in any commercial pursuit had a right to expect. It would be a very long time before any rival could give Manchester the power of talking with Darlington, Sunderland, Sheffield, Birmingham, and London; and the National Company, owing to their bold enterprise in this respect, possessed an advantage which they did not think should be taken from them by the transfer of their trunk system to the Government. If the Government took the trunk system his Company said, let them take the whole.

Mr. PROVAND, M.P., said it was not to be assumed, from what Col. Jackson had said—that the National Company had always succeeded against the Post Office because they used single wires, or that when the double wire and the single wire systems came into competition it was certain that the latter would win.

Colonel JACKSON, interposing, said he had not stated that they had beaten the Post Office because their wires were single.

Mr. PROVAND said that they opened their exchange—the Mutual Company in Manchester—last February, when they had only 100 subscribers, whereas they now had nearly 1,000, and the National Company had about 1,600. The Mutual Company had obtained for their double wire exchange about two-thirds as many subscribers in 12 months as the National Company had obtained in 10 years. Of course their rates were very different. When they began, the National Company's rates in Lancashire were £20, the same as in London. The charge of the Mutual Company was £5 to shareholders in their Company and £6 to non-shareholders. The Company was not entirely mutual, but it was strongly so, for in Manchester they had about 630 shareholders and from 1,300 to 1,400 subscribers. These were not all put on yet, but about 930 were on, and they were putting them on as fast as they could. He wished to correct an impression about the double as against the single wire. No one Man-

Digitized by Google

chester who spoke through the Mutual Exchange and who spoke through the National Company's would hesitate to say which was preferable. He was convinced that no Company would be able to give an adequate service to London until they made a double wire service all over the metropolis.

He was convinced that the National Company would not be able to give an adequate service to London until they made a double wire service all over the metropolis.

Mr. Sheriff FOSTER stated that his only interest in the discussion was as a subscriber to the telephone system. He had been glad to gather from what the Duke of Marlborough had said that there were certain persons who were prepared to give an efficient system in London at much less cost. One of the evils, he thought, from which they were suffering in London was that practically there was a total absence of competition, for the different interests had been fused.

Mr. SYDNEY MORSE said that it was evident that both Companies desired statutory powers. As a member of the public he also desired to see statutory powers granted, as then the large claims of the National Telephone Company would no doubt be curtailed. As one largely interested in electric light he thought it should be remembered, as indeed the Chairman had said, that the telephone was not the only or even the most important electrical industry. The fact that the National Company were asking powers to place their wires both over and under any road or land, and to alter the position of any electrical wires or pipes without the consent of the owners, seemed to him to have been overlooked and to require most careful attention and consideration, considering that the National Company in effect claimed an exclusive right to "earth." He also endorsed the view of the Duke of Marlborough that the Government should permit the Bills of the two telephone Companies to go into Committee, that the whole matter might be thoroughly sifted. He urged an amalgamation of the resolution and the amendment before the meeting.

The CHAIRMAN said he had been going to suggest that there was no practical difference between the resolution and the amendment, and he had ventured to make one or two alterations in the resolution which had met with acceptance by the mover. He suggested that the resolution to be put to the meeting should be as follows :—

"That in view of the importance of the telephone industry and the fact that two separate companies have Bills before Parliament, this Chamber should appoint a deputation to apply for an interview with the Postmaster-General, and express the view of the Chamber as to the supreme importance of Her Majesty's Government bringing a General Powers Bill into Parliament so as to afford facilities for the development of the telephone, not only in the Metropolis, but also with reference to inter-town services all over the country, whether by private companies or by the Government themselves."

He thought that that appeared to summarise the general view of the meeting.

Mr. JACKSON said he thought they would do well to see the Postmaster-General, particularly in reference to what the Duke of Marlborough had said—that he had heard that the Government intended to oppose the two Bills of the Companies. He thought it was very important in the interests of all present that they should ascertain what the Postmaster-General intended to do. He referred to the Association for the Protection of Telephone Subscribers, of the Committee of which he was a member, and stated that it was about to be registered as a Company, which would give them a *locus standi* before Parliament.

The CHAIRMAN stated that he thought it right to inform the meeting that, although he felt he could not grant the request, Colonel Jackson had expressed a desire to answer the remarks of Mr. Provand. He then put the resolution in the form he had suggested, and it was carried unanimously.

Various names were afterwards suggested for forming the deputation referred to, and the Chairman stated that they would be submitted to the Council of the Chamber.

The meeting then separated.

City and South London Railway.—The Parliamentary estimates of the cost of extending the City and South London Railway to Islington have been prepared by Mr. J. H. Greathead. The length of this extension is given in these estimates as 2 miles 5 furlongs 3 chains, and the total cost is set down at £706,633. Of this sum, £330,540 will, it is estimated, be spent in tunnelling, £211,000 upon the acquisition of land and buildings, £81,600 upon stations, and £13,500 for the subway for foot passengers to and from Fish-street-hill. The laying of the permanent way will absorb £15,844.

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

In this action the plaintiff claims an injunction restraining the Defendant Company from continuing to infringe letters patent,* of which he is the registered owner, for improvements in obtaining light by electricity, and in distributing currents for the same, and in the means and apparatus employed therein.

The Attorney-General (Sir R. Webster, Q.C., M.P.), Mr. J. F. Moulton, Q.C., and Mr. J. C. Graham, instructed by Messrs. Vandercorn, Hardy, Oatway and Doulton, appeared for the plaintiff. Sir Horace Davey, Q.C., M.P., Mr. Finlay. Q.C., M.P., and Mr. Roger W. Wallace, instructed by Messrs. Deacon, Gibson, and Medcalf, represented the Defendant Company.

The ATTORNEY-GENERAL, in opening the case for the plaintiff, said that this was a patent action of very great importance and of very great interest, but not either very complicated or at all difficult from the scientific point of view. Prior to the year 1878 there had been many attempts at electric lighting. They had been more or less successful, or rather, he should say, unsuccessful, in consequence of the difficulties which had arisen in finding a useful and commercial incandescent electric lamp. Prior to that time there was arc lighting. There was an intermediate stage of lighting when the Jablochkoff candle was used. Now the electric current could be generated in a variety of ways---notably in two ways—either from primary batteries or from dynamo machines. It was known at the time of the patent that you could generate a current of electricity by using a dynamo to send the current through the conductors. The conductors might be either continuous insulated wires going out and home, so that the current went right through the wire, and came back again through an insulated wire or at the other end, or at the further end the conductor might be sent to earth. "Earth" was a technical term known to electricians as any means of communicating or completing your circuit by an insulated conductor. Now having got the current generated in your conductor ready to do its work, it was necessary to fit in the lamps, and the way in which the lamps were proposed to be fitted in in all the systems at this time, was by means of what was called multiple arcs. Each of these little lamps formed a bridge, and through this bridge or across this bridge the current got back again to its destination. It must join the generator again, but instead of the lamps communicating with another conductor, they could all go to earth.

Mr. JUSTICE A. L. SMITH : What is the advantage of one over the other ?

The ATTORNEY-GENERAL : None whatever, except a question of safety from the Board of Trade point of view, or with reference to the disturbance of electric instruments in the proximity. You will be told that by the most skilled electricians.

Mr. JUSTICE A. L. SMITH : How do the Board of Trade want it to go back ?

The ATTORNEY-GENERAL : The Board of Trade expect you to have an insulated conductor going all the way, because it might be disturbing telephones, or a danger, or something else. It has nothing in the world to do with this invention, my lord. The system of lighting is perfectly useful, and, from an inventive point of view, complete, if all the conductors are taken to earth. It is a point of very great importance, and very likely a point of attack from my learned friend's point of view presently, when we understand the specification.

Things which are called secondary batteries were known for many years before 1878. Secondary batteries were batteries which stored up electricity and gave it out again when required. They were the invention of a most distinguished man named Planté. They were perfectly well known for years before 1878, but strangely enough people imagined what they are now finding out to be quite incorrect, that Planté's batteries were not sufficient and useful to do the work.

Mr. St. George Lane Fox was an electrician of the very greatest capacity and ability and of extraordinary foresight. He was no mere outsider who had made something which could not be worked, he was unquestionably far in advance of his time with regard to what he discovered as being practical, and that, both from experiments from actual user, and from trying the things himself. He knew all the theory, and proceeded to patent the first practical system and the first practicable means of successful electric lighting. The one thing that is necessary is to keep a constant current going through the lamps. If you had a lamp with a filament designed to carry a current at 100 volts, and you put 120 volts on it, the lamp would break down at once—that is to say, the current would be too strong, and the bridge would be broken down by the pressure being too great for it. Therefore, there were two reasons why the current should be kept constant ; the one that the lamp might not break down from excess, the other that the lamp might give a proper illumination, and prevent the current from getting too low Mr. Lane Fox conceived the idea, that if he interposed secondary batteries in his circuit between the generator and earth he would get a constant pressure. It was not saying too much to say that that discovery of Mr. Lane Fox had solved the difficulty of electric lighting. It was not saying too much to say that, remarkable as it may be, every system of modern successful electric lighting which proceeded from generators, dynamos, and which was absolutely maintained at a constant pressure was an exemplification of Mr. Lane Fox's discovery and system. The specification was dated October 9, 1878. It was entitled "improvements in obtaining light by electricity, and in conveying, distributing, measuring, and regulating the electric current for the same and in the means or apparatus employed therein." Mr. Lane Fox described a new kind of lamp. He need mention

* No. 3988.** 1878.

Digitized by Google

no more with regard to that lamp than to say that it was a lamp of which the conductor was platinum or iridium. It was a perfectly successful lamp from an electric lighting point of view, but it was commercially nothing like as good as a carbon conductor, and Mr. Lane Fox subsequently disclaimed that lamp. The only importance with reference to the present controversy was that it was an incandescent lamp. The Attorney-General proceeded to quote further from the specification: "The way in which I work a number of these lamps from a single source of electricity is as follows: From one pole or electrode of the electric generator or generators proceeds a large conductor, from which branch out at various points, where lights are desired, smaller conductors, which again may have conductors branching off from them and so on." It had been called a tree system—a trunk and branches. It was an identical parallel to a trunk and branches of trees. "The other pole or electrode of each electric generator is connected with the earth, so that the conductor and its branches and sub-branches will be perpetually in a state of electric tension tending to develop currents in every direction to the earth."

Mr. JUSTICE A. L. SMITH: Do I understand that it would have been just the same if they had brought it back by return conductor?

The ATTORNEY-GENERAL: Certainly, my lord, exactly—just the same. That will be the essence of my contest—identically the same from an electrical point of view, and from a practical working point of view, if brought back through a return conductor.

Mr. JUSTICE A. L. SMITH: Why does that controversy arise—in what way?

The ATTORNEY-GENERAL: It does not arise in any way unless the defendants suggest that a return to earth does not make the system which Mr. Lane Fox is describing a working system. That is the only way in which it can arise. "One pole of the electric lamp is connected with the earth, and this may be conveniently effected by means of gas or water-pipes where such exist"—that merely meant that instead of taking the wire down into the earth itself, you might take it joined on to a gas or water-pipe which went into the earth—'so that wherever the circuit is complete between the earth and any one of these branches, a current of electricity will pass through the thin leaf of metal"—that was the con-

ductor inside the lamp—"rendering it incandescent, and so produce light." "The electromotive force of the electric-conducting mains should be kept as nearly as possible constant at, say, 100 volts, or British Association units, of electromotive force." It had really a very important bearing upon this gentleman's knowledge that that which was enunciated in 1878 was to-day the best electromotive force for working lamps in any system which had been devised. "A number of Planté's (lead and sulphuric acid) cells joined together in series between the main and the earth will serve as a kind of reservoir for the electricity. The electric current may be conducted through copper conductors, which can conveniently be laid inside the existing gas-pipes, having insulators of earthenware or other material around them to prevent their contact with the iron pipes." "In order to keep the electromotive force in the electric mains constant it is desirable to have in the first place several generating machines: next, it is necessary to have some regulator such as that about to be described." Then he described a regulator. It would be contended by his learned friend that that prevented Mr. Lane Fox from saying that he used his secondary batteries as regulators, because they would say he was indicating another kind of regulator; but it would be proved that the regulator which was referred to at line 47, was a regulator for keeping the steam which drives the engine constant, or rather for keeping the amount of current which came out from the generator free from the fluctuations which would result from a different pressure of steam. Line 11 on page 4, read as follows: "The way in which I distribute the electric energy so as to work a number of these lamps from a single source of electricity is represented in the diagrams, Figs. 3 and 5, and is as follows: From one pole or electrode of the electric generator or generators (situated at *A*, Fig. 3), proceed one or more large conductors from which branch out, at various points where lights are desired, smaller conductors, which again may have conductors branching off from them, and so on. The other pole or electrode of each electric generator is connected with the earth—so that the conductor and its branches and sub-branches will be perpetually in a state of electric tension tending to develop currents in every direction to the earth. One pole of the electric lamp is connected with the earth *E*. A number of secondary batteries, such as Planté's (lead and sulphuric acid), such batteries being joined together in series between the main and the earth, will serve as a kind of reservoir for the electricity. The cells should have a very large conducting surface, and there should be several batteries connected up at various points of the mains, so that by increasing the electromotive force during the hours when not much electricity is being used they will become charged and the electric force will be stored up in them, so that a sufficient supply will be available when the electromotive force falls owing to the draft from the mains when the force is most used and needed. The number of cells in each of these batteries will depend on the electromotive force of the mains." This was a unique declaration as to the use of secondary batteries—absolutely unique. All kinds of publications were suggested by the defendants in this case, alleging that Mr. Lane Fox told the people no more than people knew before. That was a question of evidence, but he asserted that it was a unique enunciation, absolutely new, of the utility of, and the function to be performed by, secondary batteries. Mr. Lane Fox—wisely advised, from his point of view—threw overboard everything which it could be said might involve considerations except the use of his secondary batteries. He disclaimed the lamp. The regulator for regulating the steam was found not to be essential. Accordingly, he threw that overboard. Everything was cut out but the one essential novelty, which was "employment as described of secondary batteries as reservoirs of electricity in combination, with a mode or system of distribution, such as is hereinbefore explained." No doubt his lordship would wonder why this having been patented in 1878, they were fighting the case in the year 1892. The fact was Mr. Lane Fox was not a rich man. A full explanation will be given on any point as to the question of delay. The case depends entirely on the electrical evidence as to the existing state of knowledge at the date of the specification; and then it is for your lordship's construction of the specification. You will hear from the evidence what the defendants did. I shall ask your Lordship to listen with the greatest care, as I know you will do, to this. Mr. Lane Fox had to fight a combination of electric lighting companies. He made no complaint of it. Other people had recognised, but these people had declined to recognise, Mr. Lane Fox's rights.

Prof. JOHN PERRY (examined by Mr. J. C. Graham) said that he had very great experience in electrical engineering long prior to 1878, and was familiar with the state of electrical knowledge about the year 1878. The secondary battery prevented flickering of the light. That was, it regulated the supply when the dynamo was in use. When the engine which drove the dynamo went a little too fast, so that the pressure in the mains tended to be too great for the lamps, the battery stored the surplus supply of energy, When the dynamo went too slowly, giving out too little energy, the battery unstored and helped the dynamo. Precisely the same effects occurred when you altered the number of lamps that the engine was supplying. He considered the system described quite novel. It was now being used, and was a very useful invention. He knew of no description prior to Mr. Lane Fox's, or any use prior to Mr. Lane Fox's battery of secondary batteries, for the purpose of compensating the tendency to variations of pressure on the main.

Mr. JUSTICE SMITH: What were secondary batteries used for, then, before 1878?—For producing certain momentary effects.

Mr. GRAHAM: They loaded the secondary battery like a gun, and then let it off with a bang. That is what we are speaking of?—Yes.

What are the conditions that you found in Lane Fox's system which are meritorious in your mind?—

Mr. JUSTICE SMITH: If this evidence be right—I am sure I do not know whether it is right or wrong yet—but if it be right, you have plenty of merit in it, because it produces a flame that does not flicker. There is plenty of merit there. You do not want any more as regards myself. I do not know about the Court of Appeal, but if it is true I should think there was ample merit to have a steady light instead of one going up and down.

WITNESS continuing, stated that "earth" was the technical term for a return conductor, for a return however obtained. Metal return wires were also usually called "earth."

Cross-examined by Mr. FINLAY: You mentioned, I think, as the advantage of this patent that it would prevent flickering?—Yes.

Would you turn to the patent? You have the patent as amended on disclaimer. I will take it in its final form at page 4. Does not that point to the storing up of the electricity during the daytime for use at night,

Digitized by Google

a recommendation in favour of urging Government "to confer statutory powers" upon Telephone Companies.

The paragraph in question, however, is not very clear, and might be read as if the resolution were in favour of conferring such powers upon some particular company. It is evident that the Chamber, in passing any resolution of this kind, cannot act in the interest of any one company but of all telephone companies, formed or to be formed, without distinction.

I should be glad if you will kindly insert this correction, as a misapprehension appears to have arisen.—I am, Sir, &c.,

KENRIC B. MURRAY, Secretary.

February 19, 1892.

JOHNSTONE'S SYSTEM OF ELECTRICAL UNDERGROUND CONDUITS.

TO THE EDITOR OF THE ELECTRICIAN.

SIR: In your issue of the 19th inst., in which you give an account of the above system of underground conduits, you say that we appear to be "very much averse to the use of lead-covered cables." We wish to correct this statement, and to point out that what we maintain is, that lead-covered cables in an *insulated* conduit are dangerous, but in a cast-iron system, such as Johnstone's, there is no possible reason why they should not be used if desired. As a matter of fact, in America, where there are about 150 miles of duct in operation, nearly all those in New York are lead-covered, as is customary there. —We are, Sir, &c.,

THE INTERNATIONAL ELECTRIC SUBWAY COMPANY (LIMITED).

TRADE NOTES AND NOTICES.

TENDERS INVITED.—The Guardians of Wellington (Salop) Union invite tenders for providing and fitting a complete telephonic installation at their workhouse at Wellington, Salop. The installation is to consist of one centre and four sub-stations. Tenders are to be sent in to Mr. John Jones, clerk to the Guardians, not later than Wednesday, March 9th, and a copy of the specification may be seen at the workhouse. Further particulars are given in our advertisement columns, and full information can be obtained upon application to Mr. John Jones as above.

THOMSON-HOUSTON INTERNATIONAL ELECTRIC COMPANY.—This Company notify us that they have now transferred to the Union Electricitäts Gesellschaft, Berlin, their business in Germany, Austria-Hungary, European and Asiatic Russia, Finland, Sweden, Norway, Denmark, Holland, Belgium, Switzerland, Turkey, and the Balkan States; and that all business connected with the introduction and use of the Thomson-Houston systems of electric lighting, power, tramways and mining apparatus in the countries referred to will be dealt with by the Berlin house. The manager hitherto of the Hamburg office of the Thomson-Houston International Company, Mr. Louis J. Magee, will take an active part in the management of the new company as its technical director. All business in Europe in countries other than those named remains under the direct management of the Thomson-Houston International Electric Company, and will be dealt with from the General European office of the Company, No. 7, Rue du Louvre, Paris, from which office all information and estimates will be furnished. Mr. E. Thurnauer, who for several years has been in charge of the Paris office of the Thomson-Houston International Electric Company, has been appointed by the Board of Directors the General European Manager of the Company, and will have sole charge of all its affairs in Continental Europe, Great Britain, and Ireland. The London offices of the Company will remain at 35, Parliament-street, Westminster, S.W., and Mr. W. S. Graff-Baker, who has been the representative of the Thomson-Houston Electric Traction System in Great Britain, will continue to devote himself exclusively to the introduction of the system; although the lighting business for England and Ireland will be conducted as hitherto by the Laing, Wharton, and Down Construction Syndicate Limited), at 38, Parliament-street, S.W.

JOHANNESBURG.—Messrs. Woodhouse and Rawson United (Limited) send us particulars of the work done by their Johannesburg branch during the past year, which includes the first contract for the lighting of Johannesburg by means of arc lamps, which has now been running for some time; the lighting both above and below ground of the City and Suburban Gold Mining Company (Limited), Metropolitan Gold Mining Company, battery house of the Van Ryn Gold Mining Company, and the supplying direct of plant for each installation. The Company have also prepared the plans and specifications for the lighting of Pretoria, and supervised the erection of buildings, machinery, &c. Miscellaneous lighting contracts include that of the Globe Theatre, and the firm have also prepared plans and specifications for transmission of power for the Moodie's Gold Mining and Exploration Company. Sub-agencies and stores have been opened at Cape Town, Kimberley, Barberton, Pretoria, Maritzburg, and Durban.

MESSRS. HODGES AND TODD.—In our last issue we notified that a fire had recently taken place at Messrs. Hodges and Todd's premises in the Gray's Inn-road, London, W.C. We are now informed that the firm have taken new premises at 19, Kirby-street, Hatton Garden, E.C., and that they will shortly be in a position to supply their manufactures as before. We are asked to state that, contrary to some reports that have been circulated, the fire did not originate on Messrs. Hodges and Todd's premises.

GENERAL ELECTRIC COMPANY (LIMITED).—This Company have just issued the 9th edition of their catalogue of electric bells and accessories, lightning conductors, &c., and they are to be complimented upon the completeness of the book, which can safely be recommended to the trade as containing very full particulars of all this firm's manufactures. In addition to the large number of illustrations, instructions are given at the end of the catalogue for fixing and connecting electric bells, &c.

MR. A. P. LUNDBERG.—We have received from Mr. Lundberg his new catalogue and price list of electric light switches and fittings. Amongst the illustrations are shown the "Unique," the "Midget," the "Pioneer," the "Universal," the "Ridge," the "Premier," and the "Main" switches, the "Unique" combination switch wall socket, and the "Secure" ceiling rose.

PORTSMOUTH AND SOUTH HANTS ELECTRICITY SUPPLY COMPANY, LIMITED (IN LIQUIDATION).—A meeting of the shareholders is to be held at 46, St. James-street, Portsea, on March 21st, at 11, to receive the liquidator's account of the winding up.

DISSOLUTIONS OF PARTNERSHIP.—Messrs. Chant and Crawford, trading as Dollond and Co., electrical and scientific apparatus makers, Ludgate Hill, E.C. Mr. Tyson Crawford will pay all debts and continue the business.——Messrs. Dawson and East, electricians, 51, Newington-butts, S.E. Mr. G. E. East, junr., will continue the business.——Messrs. D. and G. Graham, electrical engineers, Glasgow, by the retiral of Mr. R. McPherson. The business will be carried on under the same title by Mr. John Scott, who will pay all debts.

COMPANIES' MEETINGS & REPORTS.

Westminster Electric Supply Corporation (Limited).

The ordinary general meeting of the shareholders of this Company was held on Wednesday at the Westminster Palace Hotel, Victoria-street, under the presidency of the Right Hon. Lord Suffield, K.C.B.

The SECRETARY (Mr. Frank Iago) having read the notice calling the meeting,

The CHAIRMAN said: I regret to say, gentlemen, that I am not yet sufficiently recovered from the severe illness which I have had to address you as I should have liked to do, and to answer those questions which, no doubt, you will be anxious to put. Therefore, will you allow me formally to move the adoption of the report and accounts? and I will ask my friend, Mr. Powell, to do my duty for me on this occasion, as far as explanations may go.

Mr. POWELL: My lord, before I proceed to make any remarks on the report and accounts, I am only speaking the wish of the Directors, and I am sure of all the shareholders, that you may speedily be restored to health. We have been greatly pained by the news of your long-continued illness, and we hope, now that you have come among us again, that you will soon become as strong as you have ever been in your life. I apprehend that the shareholders will take the report and accounts as read. We have now the pleasure of congratulating you upon the possession of three central stations: one in Millbank-street, which is practically completed—in fact, I do not think any more payments will have to be made in regard to this station except for some condensing apparatus; then we have the central station at Eccleston-place, which, so far as the plant and works are concerned, is almost complete; and the third station is that at Davies-street, which is almost in a similar state. At Eccleston-place we are making provision for the offices of the Company—for the secretary's office, for the offices of the engineer and his assistants, and a board room; and the erection of these buildings will be completed for an amount, the interest upon which will be very considerably less than the rental which we are paying for somewhat inconvenient premises in Victoria-street. At Davies-street we are covering the frontage with flats or chambers, erected at no very large cost, and we expect a very considerable rental from them. The buildings have all been put up in the most substantial way, and I hope that any shareholders who have the opportunity of doing so will go and see for themselves how we have combined the very best construction without being at all extravagant. I think you will all say if you see those buildings that they are an ornament to the neighbourhood in which they are situate, and I believe that they will be surrounded by buildings of a similar character. The

Digitized by Google

greatest care has been taken by our engineer to put up machinery of the best description at the lowest possible cost; and I believe it has been done most economically. We have, however, arrived at this result after a great many drawbacks. In the first place, our architect tells me that we were delayed at least 66 days by the severe frost of 1891; and, moreover, the carpenters' strike of that year delayed the Davies-street building at least six months. Yet, notwithstanding these great drawbacks, the promise which we held out at our last general meeting, that we should be able to work Eccleston-place within about a fortnight, was fulfilled more than to the letter. Within a week of that meeting we were able to start Eccleston-place by March 2nd, and on March 4th we were able to supply the light for Her Majesty's Drawing-room, with, I believe, as much perfection as characterises any of our lighting. Then, I must tell you that at the end of February of last year we had only 13,140 lamps on circuit; and to show you how the electric light current was wanted, we found that in March there was an increase of 5,842 lamps, in April of 9,992, and in May of 6,789—that is to say, an increase, in round numbers, of 22,000 lamps over the number we were supplying at the end of February; and by the end of June we were supplying about 37,000 lamps, or, in round numbers, about three times the number we had been supplying in February. When June came, however, sunlight was beginning to take the place of electricity. People were beginning to think of leaving their town residences; and notwithstanding the great increase in the number of our lamps, we found that our revenue did not increase in like proportion. The number of lamps, however, still went on increasing. In June there was an increase of 1,500 odd, in July the increase was 2,700 odd, and in August there were 2,500 more. The days then got shorter, and the increase became larger still—namely, 4,900 in the month of September. Altogether, therefore we had an increase of 11,692 lamps in these four months, which I think was very gratifying under the circumstances. Still, we found that there was no increase of revenue. The sun kept on and the people kept away; and it was not until October that we began to realise the great increase we had made in our business, while it was not until December that we found that fog was our best friend, which I believe it will always prove to be. In one week of fog our receipts increased from £800 to £1,200, or 50 per cent. Of course, this put a very heavy strain on our engineer, and all who worked under him; but I am happy to say that the supply in that week was as good as it had ever been, and it is the more gratifying for me to say that when the fog ceased, and the receipts for lighting fell down from £1,200 to their normal amount of £800, the expenses seemed to decrease almost automatically. The figures I have given you will explain why the income we showed on the 31st of December last is so small, because during the first part of the year we had comparatively few lights, and it was only as the season went on that the great increase took place; and again, it was only in November and December that we saw what a valuable business we had. Now, it may be interesting to you to know what is likely to be our income from our present circuit of lamps. I take our present circuit at the very low figure of 68,000 lamps. I may tell you that since the 31st of December the number of lamps lighted has so largely increased that we have arrived now at 75,253; but I will take the very moderate figure of 68,000, and I will take the still more moderate estimate of 10s. per lamp. That basis will show you an annual income of £34,000, instead of the comparatively small income shown in our published accounts of £19,000. Upon a lamp circuit of 68,000 we shall have an increase of revenue of £15,000; and these figures are, of course, as I have already intimated, far within the mark. We find now that our increase per month of applications amounts to something like 4,000 lamps, and we see no reason why this figure should be less, although we can hardly expect that this year we shall gain the enormous increases which were shown during last year. I am quite satisfied of this—that if we supply a good light at a moderate price, people will see that electric lighting has become one of the necessities of the age—that it is necessary for people's comfort in their houses, and that it is also most necessary for the conduct of business. In my very small experience I occasionally go to hotels, and I always choose those which have the electric light. I find that it is the best light, that it gives the least unpleasant heat, and that there are no unpleasant fumes from it. I believe that every hotel and club house will, within a very short time, be obliged to avail themselves of the light we offer them. I must again recall to your mind the very great disadvantages under which we have been during the past year. Any one who had gone to the Davies-street station this time last year would have said that it was utterly impossible for us to supply the electric light from that station for several months. Everything there was in the greatest confusion. There were a great number of excavators there, and bricklayers and labourers; and you know from your own experience in private houses how much dust there is about in connection with such work, and how destructive is the dust which they cause to machinery. Nevertheless, when we saw the very large business that was offered to us, as is shown in our monthly increases, we thought it was wise, in your interest, to put up a temporary building, and to work this business at any reasonable cost. The cost, I confess, was great, but I think the advantages were far out of proportion to the cost of producing the light. Now, having so far descanted upon what has taken place and what are our probable requirements, it may naturally occur to many of you to ask me what provision we have made for the future. I think I can tell you tolerably accurately. We find that we are supplying—or we were supplying—about 68,000 lamps. In our present premises, with our existing machinery, placed or in order, we have accommodation for about 130,000 lamps. If the space at our disposal within the existing buildings were utilised, we could supply from Millbank-street 30,000 more lamps, Eccleston-place 60,000 more, and Davies-street 75,000 more, so that altogether the existing premises could supply 165,000 lamps. That brings up our opportunities of supply to 295,000 lamps, which I will take to be, in round numbers, about four times our present output. But that is not the measure of what we can do. We find that at Eccleston-place we have very considerable space in addition, so that when the time comes we shall be able to enlarge our buildings to a corresponding extent: and I believe we shall be able to some extent to enlarge our buildings at Millbank-street. Altogether I believe that with our extra space we shall be able to supply about double the figures I have mentioned (295,000 lamps); and this, I think, is very satisfactory. I may tell you that at Eccleston-place it is probable we shall have to put up a little more machinery in order to accommodate the extra number of lamps, and I think it is not unlikely that we shall have to work Eccleston-place hard when we get to the end of our tether. I look upon it that the time must come, if Mayfair goes on as it has been, that we shall have to provide further accommodation for the Mayfair district. I will not go on with these observations any further, but I will take you to something which is more immediately pressing—that is, the amount which we shall have to allow for depreciation of machinery. You will see that in this account we have allowed £1,000, which we considered to be both fair and ample. Our machinery is new, and a great deal of it was not thoroughly worked until towards the end of the year. Nevertheless, everything wears as soon as it is put into work—as we ourselves do—and we thought it was only right that we should put a certain sum against depreciation of machinery. I must not, however, deceive you by letting you suppose that £1,000 will in any way be sufficient for the depreciation which we are likely to set against our revenue; and upon this matter I will quote from the report of our engineer, on which I believe you may thoroughly rely. He says: "I think it would be wise not to allow less than, say, £100 per week, to be set apart for depreciation, paying all maintenance charges out of revenue, in order that the Corporation may be able to meet the possibility of some new invention or improvement being so rapidly matured as to make some of our machinery prematurely obsolete, a contingency which cannot otherwise be provided for." He (the speaker) might say that their machinery now was of the very best and newest description, but electric lighting being a new invention, there was no knowing what development might take place and, therefore, he quite agreed with their engineer. He felt that he ought not to make such a remark as that he agreed with their engineer, because he was himself no one in such a matter as this, while their engineer was everyone; but he thoroughly concurred in what Prof. Kennedy said. In his report, their engineer continued: "So far as we at present know, there is no astonishing economy to be made in cost of production of the electric light. There are many economies in detail, of course, and especially cost of production will be greatly reduced as the total output increases; but all the economies before us at present must be simply the straightforward results of thoroughly good management and unremitting attention to all sorts of details. If some happy inventor succeeds in showing us how to produce light by electricity without simultaneously producing heat, there would at once be an enormous saving. Many inventors have been at work on this for a long time, but as yet without attaining any results, so far as I know, which have the slightest commercial importance. No one, however, can deny the possibility that within a reasonable number of years some such discovery may be made, although at present the very best work that has been done does not seem to have pointed out to us the right path. It is right to remember, however, that in any case boilers, steam pipes, engines, mains, and dynamos will all be required, whatever system may be the system of the future, and that although in all probability the dynamos would be quite different from those at present in use, the rest of the plant might quite possibly remain unaltered. In any case, the change of dynamos would be a change common to every supply company, and not peculiar to our own, so that we shall still be in quite as good a position as any other company." This figure of £100 has not been adopted by the Board; but I may say that we have such very great confidence in Professor Kennedy's figures that I do not doubt that we shall have to adopt them and the policy which he recommends. The tax on the energies of the Board during the construction of the works has been very heavy, and it is no small credit to those who started this Company—of whom I was not one—that they so accurately calculated the requirements of the district. They said it would require £300,000 to start this business, and we have managed to keep within that mark for the districts that were allotted to us. I should not be doing my duty if I were to claim for myself (and I am sure my colleagues would not for a moment wish to take it for themselves) the credit for these results. They have mainly been produced by the foresight, the constructive power, and the unfailing energy of Prof. Kennedy. It would be wrong of me to attempt to take credit for anything of this kind unless I put his name prominently before you. He has always kept his work well within his estimates. Not only have I been struck with his accuracy in figures, his power of design, but by his readiness to take advantage of every appliance whichhas been invented to reduce the cost of working. I should say that no Company has carried out similar works at a less cost or with greater success; and I believe that no Company within two years of its active existence has been able to supply the public with so many lamps, and so well. For that result you should in a great measure thank Prof. Kennedy. I must also single out your architect, Mr. C. S. Peach, for much praise. He has evidently entered into the spirit which has throughout animated this Board. He has worked well and cordially with Prof. Kennedy, and in every dispute that we have had—and people having to erect large buildings cannot avoid having disputes with adjoining owners—he has not only kept us free from litigation, but with the help of the common sense which he always carried about with him he has succeeded in making very good settlements for us. I must also say a few words of praise of Captain Bax, our manager, and our whole staff. Captain Bax has been most successful in obtaining customers and in dealing with them after we have obtained them. Now that our business is likely to be one more concerning administration than construction, I believe that Captain Bax will cordially work with us, and will be a grand helping hand towards carrying on the policy which Prof.

Digitized by Google

Kennedy has put forth in the report from which I have quoted to you. You will see on the wall a diagram showing the lighting we supply, the number of lamps, and the revenue; and the diagram bears out what I have told you already on these points. I have only a few other remarks to make to you, which will be chiefly in answer to a shareholder who has written to the secretary, and who wishes me to answer the question at the meeting—that is, how it is that our cost of generating electricity appears to be so high in comparison with the cost in the case of another company. Well, the reason is that that other Company began with a good business at the beginning of 1891, and that we, as you can see from the diagram, had hardly any business at all. During the whole of the year, however, we were obliged to have an engineering staff to do our small business, and it was not until we got to September or October that we paid our expenses. It could not be otherwise. We had three stations, three resident engineers, as well as a number of people about us we could not discharge—in fact we could not have carried on our business as we did, if we had not had those people about us. Therefore the cost of generating electricity appears comparatively high, but if you will go into the details, you will find our cost quite as low as theirs, and that the explanation which I have given you is ample for its purpose. I have nothing further to say. As you know, Lord Suffield has been very ill, and has been unable to undertake the duties which he so punctually discharges when he is well and in good health. I will now conclude, in seconding the motion for the adoption of the report, by saying that if any gentleman desires any explanation of the report and accounts my colleagues or myself will be most happy to give it.

Mr. WILLIAM COOPER, referring to the issue of debentures, said that nearly £30,000 appeared to have been allotted. He wished to know whether there was any great necessity for raising these debentures, seeing that in the general balance-sheet an advance of £30,000 appeared to have been made to some individual or individuals on loans. It seemed to him extraordinary that they should raise £30,000 at 5 per cent. interest, and create a permanent charge of £1,500 a-year, while they lent with the other hand what he presumed was a temporary loan. He also thought that the debentures, instead of having been allotted to applicants, should have been issued *pro rata* to the holders of shares in the Company.

Mr. POWELL: The hon. proprietor is under an entire misapprehension. At the time we borrowed money on debentures we absolutely wanted it. If we had not done so we must have stopped our works. At that time we had not issued the remaining share capital. When it was found that the works were being so rapidly pressed forward and that our lighting was increasing so very satisfactorily, people came forward and took up the remaining shares. The money was paid up for those shares, if I am correct, on the 15th of October last, but it was paid up before we actually wanted the money, and therefore, as prudent men, we had to lend that money temporarily from week to week or month to month, or by a deposit to our bankers, so as to make something out of it. It is, however, an erroneous idea to suppose that we were getting this small sum of interest for our money. At the time we actually wanted the money, as our remaining share capital was not issued. These debentures, too, are terminable in ten years, and we were really thankful at the time for people to come forward and lend us money on the terms on which we issued them.

Mr. E. P. REED said he believed it was a fact that at the time the debentures were issued their shares were unissuable at par, and were quoted in the market at a discount. In that case it was the cheapest way of proceeding to issue debentures.

Mr. COOPER said he was abroad for seven months last year, and he had no idea that the debentures were issued before the remaining share capital was placed.

Mr. FITCH stated that their coal had cost them £700 more, and their oil and water £300 more, proportionately, than the other company he had alluded to in his letter.

Prof. KENNEDY: Your figures are perfectly right. Our figures are for a whole year's working, but they cover a time of year when we were working by no means economically—that is to say, at the beginning of the year we had a temporary station at Davies-street, which was using 50 per cent. more coal per unit than we are using now; and when we first started at Ecclestone-place and Davies-street they also used, for the first three months, much more coal in proportion than they do now. You are also comparing—quite rightly—the working of this Company, beginning with 10,000 lamps in February, with the working of a Company which began with 30,000 lamps in January. That reduces the cost of wages and of coals also enormously in proportion. I have been through the accounts very carefully, and the cost for the last two quarters, when we have had a considerable number of lamps on, for coal, has been precisely that of the company you named. The total sum paid by us and by them per unit—as nearly as I can estimate their unit—has been the same; while the cost of water and oil has been a little less with us. I trust next year that we shall be much the most economical of any of the companies, but it is not quite a proper comparison to compare a year which has six months when we were working upwards and against great difficulty, with a year such as 1892, when we began fairly.

The CHAIRMAN then put the resolution, which was unanimously adopted.

Mr. HAMILTON was understood to ask when a dividend would be paid.

Mr. POWELL: We generally deal with facts and not with prophecies; and I would rather wait and see the result of six months' working. As soon as it is possible to declare a dividend we shall do so.

The CHAIRMAN: I think the proprietor will see that we are in a fair way to success, and he can therefore draw his own conclusions.

Mr. REED moved, and Mr. STRATTEN BOULNOIS seconded, the re-election of Messrs. Cooper Bros. and Co. as auditors to the Company.

The CHAIRMAN put the motion to the meeting, and having declared it carried unanimously, stated that that terminated the business of the meeting.

Professor KENNEDY: May I say, before the shareholders go, that our stations are open to their inspection? Some of you were good enough to come with me last year to Millbank-street. All the stations are now at work, and if you have time to spare to visit Eccleston-place, which is about two minutes past Victoria station, or the Davies-street station, I think you would find that either place was worth seeing. They are both in full work.

Mr. MARK STEWART, M.P., proposed a vote of thanks to the Chairman for presiding, especially under the circumstances in which he had occupied the chair, and also to the Board for the clear and lucid manner in which explanations had been given on the affairs of the Company.

Mr. COOPER briefly seconded the motion, which was unanimously adopted.

The CHAIRMAN acknowledged the vote, and the proceedings then terminated.

Birmingham Electric Supply Company (Limited).

The second annual meeting of this Company was held on the 18th inst. at the offices of the Company at Birmingham, Mr. H. Buckley presiding.

The CHAIRMAN, in moving the adoption of the report (which appeared in last week's *Electrician*), said the close of the financial year was altered from the 31st March to 31st December to meet the requirements of the Board of Trade. The accounts showed a profit of £713. 16s. 4d.; but although the number of lights on the 31st December was 5,480, that was not the number of lamps earning an income during the nine months. The average number of lamps was 3.135, or, in other words, the earning power of the 5,480 lamps was only for 5·15 months. They commenced in April with 795 lamps only, but that number increased to 5.192 lamps earning an income, although there were 5,480 on order. At the present time there were more than 6,100 lamps. The current had been taken by various classes of the community, including hotels, clubs, public buildings, institutions, restaurants, shops, banks, insurance offices, general offices, and a theatre. The demand for the light had been most satisfactory, and during the coming year it would be necessary to extend their mains and make some increase in their engines and dynamos, in order to be prepared for an extension of their business, and to meet any temporary difficulty which might occur through their plant getting out of repair.

Mr. C. A. HARRISON seconded the resolution, which was carried.

Messrs. J. F. Albright and G. H. Johnstone were re-elected Directors, and Messrs. Sharp, Parsons and Co. were reappointed auditors.

India Rubber, Gutta Percha, and Telegraph Works Company (Limited).

The twenty-eighth ordinary general meeting of the shareholders of this Company was held on Tuesday last, at the City Terminus Hotel, Cannon-street, under the presidency of Mr. S. Wm. Silver.

The SECRETARY (Mr. William J. Tyler) read the notice convening the meeting, the report of the Directors and statement of accounts being taken as read.

The CHAIRMAN: Gentlemen, I rise to move—

"*That the report be received and adopted, and a dividend of 10s. per share and a bonus of 5s. per share be paid forthwith, free of income tax, which, with the interim dividend paid in July, will amount in all to 12½ per cent. for the past year.*"

The amount carried forward is £42,000 odd, and the net profit is £79,102, after adding £25,000 to the reserve fund. Now, I wish to impress upon you the fact that the amount of our share capital is very small when we consider the nature and extent of our business. By looking at the accounts you will see that the first item of our assets and expenditure is £70,000 more than the whole of our share capital. Some shareholders do not see the advantage of our reserve fund, but it is necessary. In fact, the working capital, with the reserve added, is too small to enable us to undertake extensive contracts when offered. You must remember that cable contracts are generally large, and when two or three come to be open for tender at the same time the contractors need a large command of capital to deal with them. Now, taking all this into consideration, we think the time has come for our setting to work to increase still further our capital, and our present intention is to issue some new shares. Of course we shall issue them at a premium, and we propose to offer them to the shareholders in proportion to their holdings, so as to give to each shareholder an advantageous opportunity of increasing his stake in the Company. The machinery and buildings both here and in France are now so complete as to put us in a very favourable position as manufacturers. After these remarks I will merely add that our prospects are very encouraging, and that it is my painful duty to inform you of the death only last week of my old and esteemed colleague Mr. Neil Bannatyne.

Mr. ABRAHAM SCOTT seconded the resolution.

A SHAREHOLDER asked whether the reserve fund was considered as such, or as part of the working capital. If it was the latter, they would have between £700,000 and £800,000, instead of £416,000, on which dividend was paid. This would only give them in reality about 7 per cent.

The CHAIRMAN, in reply, said that the reserve fund was clearly stated in the assets as an investment in premises and stock, &c.—in other words, working capital. The premises in Liverpool were included in the first item under assets and expenditure. They made one amount of the whole this year.

The resolution was carried unanimously.

The CHAIRMAN moved the re-election of the retiring Directors, Mr. A. Scott and Mr. A. W. Jarvis, M.P.

Digitized by Google

The Hon. HENRY MARSHAM seconded the motion, which was carried unanimously.

The Company's auditor, Mr. J. Weise, was also re-appointed *nem. con.*

The CHAIRMAN, in replying to a vote of thanks unanimously accorded to himself and colleagues, said that such a mark of confidence would call forth renewed energies on their part to advance the interests of the Company.

Mr. MATTHEW GRAY, the Managing Director, also briefly responded, and the proceedings terminated.

Croydon Tramways Company.

The ordinary general meeting of this Company was held on Tuesday, at the Guildhall Tavern, Gresham-street, under the presidency of Mr. W. J. Carruthers-Wain, the Chairman of the Company. In moving the adoption of the report, the Chairman said he thought he might congratulate the shareholders upon the results achieved, having regard to all the circumstances of the case. In regard to the question of traction, the Directors had entered into an agreement with the Electric Tramcar Syndicate, under which that syndicate was to supply two cars to be worked by means of accumulators in turn with the horse cars working the ordinary service on the Thornton Heath lines; this Company paying a fixed sum per mile run to cover all costs of working, and including renewals and depreciation. They had had certain figures prepared showing the miles run by the electric cars since they began running. It had to be borne in mind that there were first of all various difficulties, which, of course, it would be evident to the technical mind had to be overcome, but the result had been that from the institution of these electric cars they had run 662 miles and had earned £39, which came out at the rate of 1s. 2¼d. per mile run, which he considered a marvellous return, and showed very satisfactorily in comparison with other modes of traction. He had no doubt that if this test of electric cars proved satisfactory upon the lines of this Company the Electric Traction Company would be disposed to enter into still larger arrangements for the conduct of traffic under their system. At present the work was being conducted under the principle that heads the tramway company won and tails they did not lose anything, because they were not in the position of having any money to lose or to risk in conducting a large electrical work upon their tramway. Their desire was to conduct the traffic in the most economical manner, and they were trying various means of motive power. They had recently adopted, in addition to the electrical system, a system known as the Connolly Motor. The prospects generally were encouraging, and he looked forward to the continued progress of the Company. Their relations with the local authorities, he was pleased to say, were most harmonious.

The report was adopted.

Exploration Company (Limited).

At the ordinary general meeting of this Company, held on Tuesday at Winchester House, Old Broad-street, Mr. Horace B. T. Farquhar presided.

The CHAIRMAN, in the course of his remarks, said, with reference to the Central London Railway, that he had no doubt the shareholders were all aware that two years ago some of their neighbours tried to get a Bill through Parliament to enable them to take up that project. They were, however, unsuccessful in their efforts, and last year the Board of the Exploration Company made up their minds to try themselves, as the business was a very desirable one, and one largely taken up by capitalists in America. A syndicate was formed for the purpose of running the risk and paying the law expenses and the costs of getting the Bill through Parliament; and he was happy to say that they were successful. The Bill received the Royal assent, and became law in August last. Things were now going on favourably, and before long, when financial matters improved, they would be able to carry the matter through successfully. Another company which they had been successful in floating had been the City of London Electric Lighting Company, which they brought out in conjunction with the Electric and General Investment Company.

Telegraph Construction and Maintenance Company (Limited).

The following is the report of the Directors of this Company to be submitted to the members at the twenty-eighth ordinary meeting, to be held at 38, Old Broad-street, E.C., on Tuesday, the 1st prox., at one o'clock:—

The accounts for the year show a net profit of £85,199. 8s. 5d., after charging the interest on the Debentures. To this sum must be added £61,524. 11s. 11d. brought forward from last year, making a total of £146,724. 0s. 4d. From this amount is deducted the interim dividend of 5 per cent. paid July 14, 1891, amounting to £22,410, leaving £124,314. 0s. 4d. to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2. 8s. per share, or 20 per cent., free of income tax, leaving £57,084. 0s. 4d. to be carried forward to the next account.

All the Company's steamships have been employed during portions of the year 1891 in laying or repairing submarine cables in various parts of the world.

Repairs have been effected in the Brazilian Submarine Telegraph Company's cables in the vicinity of Lisbon and Madeira, and in the Direct United States Company's cable on the coast of Nova Scotia. A duplicate cable has been laid for the Eastern Extension Telegraph Company between Madras and Penang, and a triplicate cable for the Eastern Telegraph Company between Aden and Bombay. A cable has also been laid for the Great Northern Telegraph Company between Oye, on the French coast, and Fanoe, on the coast of Denmark. During the year a length of 5,132 knots of telegraph wire has been insulated for submarine and land lines.

The Company's steamships, and factories at East Greenwich and Wharf-road, are in efficient condition.

The Directors regret to announce the death, on August 12th last, of Sir Thomas Fairbairn, Bart., who had served on the Board for a period of over 21 years. Their former colleague, Admiral of the Fleet Lord John Hay, G.C.B., being again free from service afloat, has been re-elected to a seat at the Board in the place of Sir Thomas Fairbairn.

The retiring Director is Mr. George William Campbell, who, being eligible, offers himself for re-election. The meeting will have to appoint auditors for the ensuing year. Mr. John Gane (of the firm of Messrs. Gane, Jackson and Jefferys) and Mr. Patrick A. Glegg (of the firm of Messrs. Welton, Jones and Co.), who retire, offer themselves for re-election.

NEW COMPANIES, STATUTORY RETURNS, &c.

[*In addition to the information given under this heading, detailed particulars of the majority of the Companies whose returns appear below will be found in* "THE ELECTRICIAN" ELECTRICAL TRADES DIRECTORY AND HANDBOOK.]

DALMATIAN EXPLORATION AND MINING SYNDICATE (LIMITED).—Among the objects of the above-named Company, which was registered on February 15th, with a capital of £500, in £1 shares, is included that of acquiring, manufacturing, working, letting out on hire, or otherwise dealing with or disposing of plant, machinery, apparatus, and materials for the production and distribution of electricity, and for the application of electricity to the separation of metals and ores, as well as for lighting, heating, or motive power, and to supply electricity. Presented for registration by Arnold, Williams, and Co., The Vestry House, Laurence Pountney-hill, E.C.

ELECTRO-AUTOMATIC FIRE EXTINGUISHING COMPANY (LIMITED).—This Company was registered on February 16th, with a capital of £12,500, divided in 6,940 ordinary, 5,500 cumulative preference, and 60 founders' shares of £1 each, by Fox and Joy, 59 and 69, Chancery-lane, W.C. The objects are to enter into and carry into effect an agreement which has already been prepared and is expressed to be made between C. M. Martin, of No. 8, Imperial-buildings, Holborn Viaduct, E.C., of the one part, and the above-named Company of the other part; or otherwise to acquire the exclusive licence mentioned in the said agreement or the letters patent mentioned in the schedule to such exclusive licence and all the extensions of the said letters patent or any of them; and to carry on the business of a manufacturer and vendor and lessor of fire checks or fire extinguishing apparatus and all materials and apparatus necessary for making the same. Registered without Articles of Association.

FLETCHER, RUSSELL AND CO. (LIMITED).—This Company was registered on February 16th, with a capital of £150,000, divided into 5,000 Six per Cent. Preference and 10,000 ordinary shares of £10 each, by Cunliffes and Davenport, 43, Chancery-lane, W.C. The objects are to acquire the goodwill of the businesses carried on at Warrington, in the County of Lancaster and elsewhere, under the style of Thomas Fletcher and Co., as gas engineers, and at Pendleton, near Manchester, in the said county, and elsewhere, under the style or firm of W. and A. C. Russell and Co., as artistic and general ironfounders, and to carry on the businesses of iron and metal founders, mechanical, gas, heating, lighting, ventilating, electrical and general engineers, iron and brass workers, machinists, tool makers, smiths, &c.

HARFIELD AND CO. (LIMITED).—This Company was registered on February 16th, with a capital of £100,000 in £10 shares, by Williams and James, Norfolk House, Thames Embankment, W.C. The objects are to acquire the business carried on by William Harfield and Co. at Mansion House-buildings in the City of London, and under the style or firm of the Blayden Ironworks, at Blayden-on-Tyne, and to carry on the business of mechanical engineers, machine and engineering tool makers, boiler makers, iron founders, brass founders, metal workers, electrical engineers and manufacturing chemists, &c.

DISTRICT MESSENGER SERVICE AND NEWS COMPANY (LIMITED).—The first annual return of the above-named Company, made up to January 14, 1892, was filed on February 8th. The Company was registered on June 30, 1890, with a nominal capital of £200,000, divided into 39,800 ordinary and 200 founders' shares of £5 each. Among the patents acquired were included the following:—An invention of "Improvements in Electrical Signalling Apparatus for Police Service and the like," for which provisional protection for the United Kingdom, No. 6,126, was granted to R. D. Radcliffe on April 22, 1890; and an invention for "Improvements in and relating to Printing Telegraphs, and to the Distribution of News transmitted thereby," for which provisional protection, No. 8,031, was granted to the said R. D. Radcliffe on May 22, 1890. At the time of making up, 12,567 ordinary and all the founders' shares were taken up, of which 7,411 ordinary and the 200 founders' shares were issued as fully paid. Upon 4,389 of the remaining ordinary shares £3 10s. per share has been called, and upon the remaining 767 ordinary shares £3 per share has been called, resulting in the payment of £14,923. 10s., and leaving £2,739 in arrears. Registered office: 50, Lime-street, London, E.C.

EASTERN TELEGRAPH COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 28, 1892, was filed on February 18th following. The Company was registered on June 6, 1872,

Digitized by Google

with a capital of £3,800,000, in £10 shares (of which 339,700 shares were issued as fully paid up), to acquire the undertakings, telegraph lines, property, privileges, effects, obligations, and the liabilities of the following four companies, namely, the Anglo-Mediterranean Telegraph Company (Limited), the British Indian Submarine Telegraph Company (Limited), the Falmouth, Gibraltar, and Malta Telegraph Company (Limited), and the Marseilles, Algiers, and Malta Telegraph Company (Limited). The present nominal capital is £4,700,000, divided into 70,000 preference and 400,000 ordinary shares of £10 each. At the time of making up, 469,988 shares were taken up, the full amounts called on both preference and ordinary, and all calls paid. Registered office: Winchester House, 50, Old Broad-street, London, E.C.

J. E. H. GORDON AND COMPANY (LIMITED).—The first annual return of the above-named Company, made up to the 8th February, 1892, was filed on the 16th February following. The Company was registered on the 19th September, 1890, with a capital of £50,000 in £10 shares, to acquire and carry on the business of J. E. H. Gordon, electrical engineer. At the time of making up, all the shares were taken up, of which 3,000 were issued (2,000 to J. E. H. Gordon and 1,000 to W. J. Rivington) as fully paid in full satisfaction of the purchase consideration; upon the remaining 2,000 shares the full amount has been called, resulting in the payment of £19,970 and leaving £30 in arrears. The principal shareholders are J. E. H. Gordon, M.Inst.C.E. (2,150), W. J. Rivington (1,350), S. W. Searle (156), S. Woodhouse (300), S. H. Woodhouse (200), E. H. Fowle (645), and H. R. Bruxner (100). The following notice was filed on February 16, 1892:—"Notice of Increase of Capital of J. E. H. Gordon and Company (Limited). To the Registrar of Joint-Stock Companies. J. E. H. Gordon and Company (Limited) hereby give you notice, in accordance with 'The Companies Act, 1862,' that by a resolution of the Company, dated February 8, 1892, the nominal capital of the Company has been increased by the addition thereto of the sum of £50,000, divided into 5,000 shares of £10 each, beyond the registered capital of £50,000. Dated February 9, 1892. J. E. H. Gordon and Company (Limited), Hy. Sinclair, secretary." Registered office: 11, Pall-mall, London, S.W.

LAMP MANUFACTURING COMPANY (LIMITED).—The statutory return of the above-named Company, made up to date to January 3, 1891, was filed on November 24, 1891. The Company was established to acquire the patents and assets, and to carry on the business of Ridsdale's Railway Lamp and Lighting Company (Limited), and to carry on the business of manufacturers of, and dealers in, lamps of all kinds, and of apparatus connected with the manufacture, consumption, and supply of gas, oil, and electricity. The English and Scottish Trust (Limited), of 11, St. Helen's-place, London, E.C., are the largest shareholders. Registered office: 45, City-road, London, E.C.

MACMAHON'S PATENT ELECTRIC CHECK SYSTEM (LIMITED).—The statutory return of the above-named Company, made up to the 18th July, 1890, was filed on the 15th February, 1892. The Company was registered on the 6th March, 1890, with a capital of £30,000 in £10 shares, to acquire and work certain patents, particulars of which were not given. The patents and rights to be acquired to be fully satisfied by the allotment of 1,000 fully paid-up shares to Francis E. MacMahon or his nominees, and 1,000 fully paid-up shares to Charles H. Ashley or his nominees. The first annual return of the same Company, made up to January 14, 1892, was also filed on February 15, 1892. The whole of the shares have been taken up, and 2,000 issued as fully paid. Upon the remaining 1,000 shares £5. 7s. 6d. per share had been called, resulting in the payment of £4,943. 15s., and leaving £431. 5s. in arrears. The principal subscribers are Charles H. Ashley, of Thirsk Lodge, Hornsey-lane, Highgate, London, N. (1,005), and Edwin Williams, of 3, Finsbury-circus, London, E.C. (721). Francis E. MacMahon, who, in the preceding return, held 450 shares, has sold all his shares in the Company. Registered office: 24, Great Windmill-street, Piccadilly, London, W.

MAQUAY SYNDICATE (LIMITED).—The annual return of the above-named Company, made up to the 25th December, 1891, was filed on the 30th December following. The Company was registered on the 28th September, 1889, with a capital of £12,000 in £100 shares, to purchase and acquire or to enter into arrangements for the option of purchasing and acquiring the benefit of the inventions for an improved voltaic battery, for improved means for feeding electric batteries, and for removing the plates therefrom, and for a miners' lamp respectively, protected by letters patent, No. 15,040 of 1885, No. 990 of 1887, and No. 14,932 of 1888, to test and work the said patents, and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity and manufacturers of electrical apparatus. At the time of making up, 92 shares had been taken up, of which 60 had been issued as fully paid. The full amount has been called on 29 of the remainder, resulting in the payment of £2,550 and leaving £350 in arrears. The principal shareholders are:—Sir Redvers H. Buller, K.C.B. (10 £100 shares); Sir Edward R. Sullivan, Bart. (51); W. H. Gramshaw, of the Stock Exchange, E.C. (15); and Samuel W. Maquay (9). Registered office: 9, Frith-street, Soho-square, London, W.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The fourth annual return of the above named Company, made up to February 9, 1892, was filed on February 18th following. The Company was registered on March 2, 1888, with a capital of £100,000, divided into 19,980 ordinary shares of £5 each, and 100 founders' shares of £1 each. The Company, however, passed on March 2, 1891, and confirmed on March 20, 1891, special resolutions by which the capital was raised to £200,000 by the creation of 20,000 Seven per Cent. Preference Shares of £5 each, and new Articles of Association were adopted. At the time of making up (February 9, 1892), 18,680 ordinary, the 20,000 Seven per Cent. Preference, and the 100 founders' shares were taken up, £5 per share called on the ordinary and preference, and £1 called on each of the founders' shares, and all calls paid, resulting in the total payment of £193,500. Registered office: Mason's-yard, Duke-street, St. James's, London, S.W.

MINING AND GENERAL ELECTRIC LAMP COMPANY (LIMITED).—The annual return of the above-named Company, made up to January 27, 1892, was filed on February 2, 1892. The Company was registered on November 24, 1888, with a capital of £100,000 in £1 shares, to acquire certain patents relating to the production, supply, or utilisation of electricity or electrical currents, from the New Portable Electric Lamp and Power Syndicate Company (Limited), and to carry on the business of manufacturers of lamps of all kinds and of apparatus connected with the manufacture, consumption, and supply of electricity. An agreement made March 29, 1889, with J. H. Hays and B. Nicholson, the liquidators of the New Portable Electric Lamp and Power Syndicate Company (Limited), fixed the purchase consideration at £80,000 to be satisfied by the payment of £17,695 in cash, £20,000 in fully paid-up ordinary shares, and the remaining £42,305 in cash or fully paid-up shares at the option of this Company; and it was also agreed that 8,190 shares (in addition to the above 20,000) should be issued to the nominees of the New Portable Electric Lamp and Power Syndicate Company (Limited). An agreement made on March 28, 1890, between the same parties, determined that the balance of the above purchase consideration (£34,115) should be fully satisfied by the allotment of 34,115 ordinary fully paid up shares to the nominees of the New Portable Electric Lamp Company. At the time of making up (January 27, 1892), 91,500 out of the total of 100,000 shares, had been taken up, of which 62,305 had been issued as paid in accordance with the above agreements. Upon the remaining 29,195, the full amounts had been called and paid. The principal subscribers are Mrs. T. C. Baring (20,000 shares), Daniel de Castro (2,000), Henry Hoare (10,564), Nevil Maskelyne, M.P. (11,064), B. Nicholson (7,346). Registered office: 11, Abchurch-lane, London, E.C.

MORECAMBE ELECTRIC LIGHT AND POWER COMPANY (LIMITED).—The statutory return of the above-named Company, made up to November 30, 1891, was filed on December 9th following. The Company was registered on July 27, 1891, with a capital of £15,000, divided into 14,950 ordinary and 50 founders' shares of £1 each, to acquire the rights and powers of Thomas Reginald Andrews and Thomas Preece, the undertakers of the Morecambe Electric Light and Power Order of 1890, of and in the undertaking authorised by that order and to carry on the business of electricians, mechanical and electrical engineers, suppliers of electricity and manufacturers of and workers and dealers in electricity, electric motive power and electric light. At the time of making up, 32 founders' and 2,136 ordinary shares were taken up, of which 360 ordinary shares were issued to Messrs. Andrews and Preece (Limited), electrical engineers, as fully paid. Upon the founders' shares, the full amount has been called, and upon the remaining 1,776 ordinary shares, 4s. per share has been called, resulting in the payment of £339 15s. 0d., and leaving £47 9s. 0d. in arrears. The majority of the shares are taken up by the inhabitants of Morecambe and Bradford. Registered office: 18, The Crescent, Morecambe, Lancs.

MULHOLLAND, MAUGHAM AND CO. (LIMITED).—The first annual return of the above-named Company, made up to November 5, 1891, was filed on the following day. The Company was registered on July 29, 1890, with a capital of £5,000, divided into 120 founders' and 380 ordinary shares, of £10 each, to acquire the business carried on by R. M. L. Mulholland and B. Maugham, at Ferryhill, Durham, and to carry on the business of mechanical and electrical engineers, manufacturers and dealers in all kinds of apparatus required for or capable of being used in connection with electrical engineering, and in particular to construct, lay down, establish, fix and carry out all necessary cables and other works for such purposes. At the time of making-up, 120 founders' and 107 ordinary shares had been taken up. Upon the founders' the full amounts per share have been called, while upon the ordinary shares £5 per share has been called and paid, resulting in the payment of £1,735. Registered office: West Cornforth, R.S.O., Ferryhill, Durham.

MUTUAL TELEPHONE COMPANY (LIMITED).—The first annual return of the above-named Company, made up to January 14, 1892, was filed on February 19th. The Company was registered on February 4, 1892, with a capital of £100,000, in £10 shares. By a resolution of the Company in general meeting, held on July 21, 1890, it was resolved to increase the capital to £350,000 by the creation of 25,000 new shares of £10 each. At the time of making-up (January 14, 1892), 4,135 shares had been taken up, a call of £8 per share made, and £31,750 paid, leaving £1,330 unpaid. Most of the shareholders reside in Manchester and district. Registered office: 10, Tokenhouse-yard, London, E.C.

CITY NOTES, &c.

BRUSH ELECTRICAL ENGINEERING COMPANY (LIMITED).—The Stock Exchange Committee have ordered the 5,004 additional preference shares, Nos. 69,997 to 75,000, to be quoted in the Official List.

CITY AND SOUTH LONDON RAILWAY COMPANY (LIMITED).—The traffic receipts for the week ended February 21st were £872, as against £718 in the corresponding period of last year, showing an increase of £154. The total receipts to date, from January 1st, 1892, are £6,227, against £5,479, an increase of £748.

DIRECT SPANISH TELEGRAPH COMPANY (LIMITED).—The Board has, upon the accounts for the half-year ended December 31st being submitted, decided, subject to audit, to recommend the payment of dividends at the rate of 10 per cent. per annum on the Preference shares, and at the rate of 4 per cent. (free of income-tax) on the ordinary shares, making with the previous half-year's dividend a total distribution of 4½ per cent. for the year on the ordinary.

Digitized by Google

HALIFAX AND BERMUDAS CABLE COMPANY (LIMITED).—The Stock Exchange Committee appointed yesterday (Thursday) as the special settling day in the £120,000 Four and a-Half per Cent. First Mortgage Debentures of this Company.

ST. JAMES' AND PALL MALL ELECTRIC LIGHT COMPANY (LIMITED).—The Stock Exchange Committee have ordered the 10,000 additional preference shares, Nos. 30,081 to 40,080, to be quoted in the Official List.

SANITAS COMPANY (LIMITED).—Mr. F. H. L. R. Moll presided on Tuesday last at the fifteenth ordinary general meeting of the shareholders of the Sanitas Company, and announced a dividend of 10 per cent. for the past year. In the course of his remarks, the Chairman congratulated the shareholders on the great increase in the use of the Company's preparations, and insisted upon the value of Sanitas as a means of preventing the spread of epidemics in large establishments, where considerable numbers of *employés* are working together. Mr. Moll was subsequently re elected a Director of the Company, on the motion of Mr. Kingzett.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY (LIMITED). Notice is given that the transfer books of this Company will be closed from February 22nd to March 1st, both days inclusive, preparatory to the payment of dividend.

WEST INDIA AND PANAMA TELEGRAPH COMPANY (LIMITED).—The Stock Exchange Committee have appointed this day (Friday) as a special settling day in the £80,000 Five per Cent. Debentures (1917) of this Company, and have ordered the debentures to be quoted in the Official List.

THE ELECTRICIAN:

A WEEKLY LLUSTRATED JOURNAL OF

ELECTRICAL ENGINEERING, INDUSTRY AND SCIENCE.

No. 720.—Vol. XXVIII. FRIDAY, MARCH 4, 1892. PRICE FOURPENCE. *Annual Subscription (U. K.), 19/*

NOTES.

We regret to learn that the Sunbeam Lamp Company has been compelled by the Edison-Swan Company to suspend their manufacturing business. Their high candle-power lamps possessed several advantages, and it is not surprising that the Edison-Swan Company has taken decided action; indeed, it is somewhat of a mystery why nothing was done before. We are given to understand that the ball was opened a few months ago by warnings given to customers of the Sunbeam Company. This *modus operandi* has the sanction of long usage, but is none the less injurious to the best interests of the electrical industry at large.

It is sincerely to be hoped that the system of Pioneer Companies will not bring electrical enterprise into such disrepute as the parent and sub-company systems at one time succeeded in doing. The financial manœuvres which took place at the time of the promotion of the City lighting yielded the original speculators a sum of money, called a bonus, amounting to 50 per cent. on their investments; although the starting of that enterprise is so far from being an engineering success that the contractors have had to plead for extension of time, and appear to have met with difficulties which were unforeseen, at all events by themselves. The certainty of a demand for the electric light in the City, and the absolute monopoly of the undertaking—for a failure to execute the contract was not dreamed of—were two sources of strength to the "pioneers." Following on this "success," the Central London Electric Railway appears now to have fallen into the hands of similar financiers.

The New Telephone Company, originally started with the object of providing a transmitter which should be free from the great monopoly, threatened at one time to enter the field with a subscribers' service. The transmitter was declared to be an infringement, and was crushed; and the New Telephone Company ceased to do business, but not before it had secured a twenty years' licence from the Postmaster-General. The New Telephone Company is, we regret to hear, also to be pioneered. The term "pioneer" is absurd in the face of some fifty thousand telephone subscribers in the country and in London. The New Company has not, nor can it hope to have, any monopoly whatever, but it proposes to compete against a well-established system. The New Company starts with a licence, a Bill before Parliament which is opposed by the Post-office, and, it is suggested, the privilege of running its wires in the casings which are now being laid by the City of London Electric Lighting Company. The one essential object of any telephone system is to enable any one subscriber to be placed in communication with any other. No suggestion has yet been made of any plan for connecting subscribers of the new Company with those of the old, unless indeed in our leading article last week, and that appears to be quite impracticable. All the present subscribers want a better service, a large majority wants a cheaper one. The National Telephone Company is really trying to amend the service; and it seems much more likely to succeed in pleasing its subscribers, or in being taken over by the Post-office, than to be swamped by a competing concern.

The great use of diagrams to represent in a clear, brief, and speedy way the essential parts of apparatus referred to by the author of a Paper is sufficiently obvious; and now that alternate and multiphase currents have so increased the complexity of electrical methods of distribution, it is of as much importance for the writer of an article to describe his work by means of a well-arranged diagram as by clearly expressed sentences. The meaning of a diagram can be very rapidly grasped if the signs used to denote currents, electromotive forces, magnetic poles, &c., are such as one is familiar with; and it is thus desirable that a uniform system of signs should be adopted. M. Hospitalier, in his excellent work on Electrical Energy, has consistently used throughout his book some very good diagram signs; and Professor S. P. Thompson, on Friday last at the Physical Society, made a number of useful suggestions in this direction. We are compelled to hold over a description of these owing to pressure on our space.

While it may be impossible to get authors to adopt the same symbols in the analytical expressions occurring in their writings, it will be generally admitted that such uniformity would much diminish the length of time and the amount of thought needed by the average reader to grasp the meaning conveyed. But although this uniformity may be impracticable for algebraic symbols, it does not seem so much so for diagram signs, the importance of which is even greater, since they appeal not only to those who read the algebra but to those who skip it.

In our issue of December 25, 1891, we referred to a violent dispute which was said to have arisen between Prof. Elisha Gray and the American Institute of Electrical Engineers, with regard to the proposed International Electrical Congress at Chicago; a Congress which we ventured to opine would prove the most promising international feature of the Exhibition if conducted on sound lines. Subsequently in our issue of January 22nd, our New York correspondent stated that the unfortunate difficulty was at an end, "Prof. Gray having seen the advisability of acceding to the propositions of the Institute." We now hear on excellent authority that this statement by no means represents the facts. "The electrical journals here have quite persistently represented a conflict between the American Institute of Electrical Engineers and the local Committee on World's Electrical Congress, appointed by the Exposition authorities. Prof. Gray says that from the first the officers of the Institute of Electrical Engineers have entirely disclaimed any opposition or feeling on the subject. They have met Prof. Gray with great cordiality, and with a disposition to co-operate harmoniously with the Committee on the Congress. The Committee of the Institute has done everything asked by Prof. Gray cheerfully and without hesitation." These statements are borne out by the following resolution passed at a meeting of the Council of the Institute:—

Resolved, That the American Institute of Electrical Engineers, having already taken action during the past three years, by correspondence and otherwise, towards the holding of an International Electrical Congress in connection with the Columbian World's Fair, hereby expresses its desire and intention to co-operate, by all means in its power, with the World's Congress Auxiliary of the World's Columbian Exposition, through its Electrical Congress Committee, in furthering the gathering of such a Congress at Chicago in 1893, and in making it a successful and worthy representation of the best electrical science and practice in all parts of the world.

Our leading magneticians hold that all substances are magnetic under appropriate conditions. That being so, would it not be worth while to inquire whether the requisite concatenation of circumstances did not obtain at the last meeting of the Institution of Electrical Engineers? Speaker after speaker arose, gazed wistfully at the brilliant assembly, and then little by little was drawn towards the blackboard, like iron dust to a magnet, and before long was flattened against its polar surface, there to remain until dissipated by the rising temperature of the audience and presidential pressure. All felt this mysterious influence; the μ's of the professor and the engineer were sensibly the same. Nothing indeed but the "reluctance" of the assembled members prevented even the rubber and fibre champions from doing battle on the board by the aid of powerful operators and convenient approximations.

The algebraic symbols were more than usually microscopic, the surface of the board was abnormally bad, and 90 per cent. of the tangled expressions were invisible amidst the encircling gloom cast by ponderous overhanging diagrams. That *rara avis* a "typical higher harmonic" was at one time on view, and we were desired to inspect it; our ocular organs not, however, being sensitive to Hertz oscillations, we were unable to see through the head of one professor and the body of another; so that the intellectual treat was entirely missed by us. Exactly what we lost, we don't quite know; but we feel sure it was something good.

In view of the renewal of these mathematico-gladiatorial displays we would urge every member of the Institution to arm himself with a pair of Sam Weller's double-million magnifying glasses; unless the formulizers will take pity and provide a sufficient number of lithographed sheets of their equations, though perhaps they really concoct them on the spot. This we doubt.

Blackpool.—The Electric Lighting Committee have decided to recommend the Council to extend the electric lighting.

Personal.—The Council of the Gas Institute has, we understand, nominated Mr. Denny Lane, of the Cork Gas Consumers' Company, as president, in succession to Mr. Valon.

McGill University.—Prof. Carus-Wilson, the newly-appointed instructor in electrical engineering at this University, is at present engaged in re-arranging and extending the course.

Birds of a Feather.—The President of the Electropathic and Zander Institute complains that a man is going about London "committing a most impudent fraud on the public."

St. Pancras Vestry.—This vestry has given notice of the withdrawal of the deposited Bill, under which powers were sought to borrow £360,000 for the electric lighting of the whole of the parish.

Lord Kelvin.—Lord Kelvin (Sir W. Thomson) took the oath and his seat, in the House of Lords, on his elevation to the peerage, on Thursday last. He was introduced by Lord Rayleigh and Lord Sandford.

British Association.—The Edinburgh meeting of the British Association will commence on Wednesday, August 3rd. On Monday evening, August 8th, a discourse on magnetic induction will be delivered by Prof. J. A. Ewing, F.R.S.

Indian Telegraphs.—The telegraph has been extended from Bhamo to Nampoung post on the Chinese frontier. There is now a gap of only 65 miles between the terminus of the English wire and the Chinese telegraph station at Momein.

Obituary.—The death is announced of Sir John Coode, K.C.M.G. Sir John Coode was born in 1816, and began his career under the eminent engineer Rendell. He was President of the Institution of Civil Engineers in the years 1889 and 1890.

Inland Telegraph Money Orders.—On Tuesday last this system, which has hitherto been in operation only at head and branch offices, was extended to all post offices in the United Kingdom at which telegraph and money order business is transacted.

Worcester.—At the meeting of the Watch Committee last week it was reported that fifteen tenders had been received for the supply of electric light under the provisions of the Council's Order; and Mr. W. H. Preece was engaged to advise the Council on the tenders.

Electric Tramways for Madras.—It is stated that Messrs. William Hutchinson and Co., of London, intend to bring out a company for the construction of electric tramways in Madras. The Madras Government has authorised the project. The overhead conductor system will probably be adopted.

Electric Lighting at the Mansion House.—In consequence of an important engagement the Lord Mayor and Lady Mayoress were unable to be present at the proposed electrical private view at the Mansion House, announced for Tuesday last; and, therefore, it was postponed until Monday, March 7th.

Digitized by Google

Institution of Civil Engineers.—At the ordinary meeting of this Institution on Tuesday, March 1st, it was announced that the monthly ballot had resulted in the election of three honorary members, viz.:—Dr. Werner von Siemens, Field-Marshal Sir John Lintorn Simmons, and Sir George Gabriel Stokes, Bart.

Old Students' Association.—The Paper on "The Behaviour of Insulating Materials under the Action of High Potential Differences," which will be read on Friday next before this Association by Messrs. H. B. and W. Fox Bourne, will be illustrated by large scale experiments with a transformer giving 50,000 volts.

The House to House Electric Supply Company.—We are informed that the words quoted from Mr. Gay's letter in our last issue, "The total period during which this portion of the lights were out averages about one hour," means that the longest period during which any of the lights were out was under two hours. A clear statement of the time of the break-down and the time at which the engines were re-started would have saved us from referring to other information which appears to have been inaccurate.

A Cold Galvanising Process—The usual process of coating iron or steel articles by steeping them in molten zinc is somewhat wasteful of zinc, and has the disadvantage of reducing the strength of wires. The London Metallurgical Company has recently introduced a cold process, for which they claim the following advantages: a better protection to the iron for an equal thickness, and a better adhesion, for the same cost. Mr. Arnold Philip, Assoc. Royal School of Mines, F.I.C., F.C.S., has reported favourably on the process.

Patent Specifications.—A uniform price of 8d. will in future be charged for all printed specifications. Over 10,000 of these are issued every year, and up to the present time the price of each varied from 3s. to 4d. Henceforth any specification in stock can be obtained from the Patent Office at 8d.; and arrangements have been made with the Postmaster-General by which postal requests in the form of a postcard, price 8d., will be on sale at each post-office, so that any one knowing the number and year of a particular patent may, on filling in the blanks on the card, have a copy of the specification delivered at his address by return of post, without further expense or correspondence.

Antwerp.—At its meeting on Friday last the Conseil Communal adopted the electric lighting scheme of MM. Moris and Van Rysselberghe. These gentlemen will have to deposit immediately as a security the sum of £20,000, and a second similar sum within six months. They are to establish an hydraulic network for the supply of water at 150lb. pressure, and may also run underground electric mains. The town may within four years demand an electric supply for street lighting, the current to be paid for on the sliding scale plan. At the end of 25 years the current will be supplied to the public lamps gratuitously, and the concessionnaires will be freed from any municipal tax, and allowed to make use of overhead wires.

The Telephone in Parliament.—On Thursday, last week, Dr. Cameron asked the Postmaster-General whether he was yet in a position to announce the decision of his department on a question stated by his predecessor to have been under consideration at the beginning of last Session—the granting of licences for telephone exchanges to applicants proposing to introduce loud-speaking and other improved forms of telephone, which had become available through the expiration of the principal telephone patents in July last. In reply the Postmaster-General stated that the subject was part of one of a much wider scope which had occupied his attention ever since he entered upon his present office, and which was being considered by Her Majesty's Government; but, speaking generally, with regard to the grant of additional licences, each application must be considered upon its individual merits.

The French Electrical Tariff.—At the last meeting of the Syndicat Professionel des Industries Electriques, which played such an important part in securing the imposition of protective duties on electrical goods entering France, it was stated that the Government had originally entirely forgotten to tax anything electrical except arc-light carbons. The efforts of the Syndicat met with varying degrees of success. A 20 per cent. *ad valorem* duty was asked for in the case of incandescent lamps, but not more than 8·5 per cent. was obtained. On the other hand, only a 20 per cent. duty on arc-light carbons was asked for; but duties ranging from 15 per cent. to 22 per cent. have been imposed in the general tariff; and similarly in the case of dynamos duties ranging from 5 per cent. to 20 per cent. have been imposed, while 10 per cent. only was asked for.

An Ingenious Electric Automatic Machine.—An ingenious automatic machine has been established near the letter-box at Charing-cross for the collection of letters to be forwarded by the Post Office Express Service. It is in electrical connection with the postal telegraph office opposite the station. By dropping a penny into the slot and pulling out the slide, a brown-coloured envelope is delivered. This envelope contains another envelope and a card. The communication is intended to be written on the card, which is then enclosed in the white envelope, and this, with the fees for delivery, which have been fixed at threepence per mile, is re enclosed in the outer envelope and deposited in the box behind the flap which bears the printed instructions. The act of withdrawing the slide sends the call signal to the telegraph office, and a messenger is at once despatched to collect the special letters.

The Telephone Companies' Bills.—Mr. R. G. Webster will move, after the Second Reading of the Telephone Companies Bills, that they shall be referred to a Hybrid Committee, with a view to the consideration of the advisability of introducing provisions which will put the telephone companies generally on a similar footing to that on which the gas and water companies are placed by existing Acts.——The Bills will meet with strong opposition before reaching the Committee stage. In the case of both Bills, Mr. Kimber has undertaken to move their rejection on second reading; and in the case of the New Telephone Company's Bill, Sir Albert Rollit has also given notice to move its rejection. Petitions against the National Company's Bill have been presented by more than 170 Local Authorities, by nearly 50 Gas, Water, Railway, and Electric Supply Companies, and by some 10 property owners. Against the New Telephone Company's Bill 60 Local Authorities, 20 Companies, and 8 property owners have petitioned.

Cable and Land Line Interruptions and Repairs:

	Date of interruption.		Date of repair.
	1891.		1891.

Electric Insurance.—"It is reported," says *Industries*, "that during the Electrical Exhibition the Crystal Palace insurance rates have been raised some 30 per cent. . . The harm done to the electric light industry by this ill-advised action of the insurance companies is incalculable. It is as if they said that electric lighting is dangerous, whereas the whole object of the Exhibition is to show that electric lighting is now practically perfect. . . There are two ways out of difficulties of this sort. One is not to insure at such onerous rates, but to take the small risk without insuring at all; another is to insure elsewhere. There is now a splendid opportunity for starting an electrical insurance company." The idea of an electrical insurance company is, of course, no new one, but previous preliminary attempts to form such a company did not meet with much support in financial circles. But perhaps the time has now come for a renewed endeavour.

The London Telephone Service.—"The real secret of the business," says the *Economist*, "is that the National Telephone Company has to pay dividends upon a capital that was watered to the extent of over 50 per cent. when the amalgamation with the United, Lancashire and Cheshire Companies took place in 1889. . . . Since the amalgamation the dividends have been modestly restricted to 6 per cent.; but 6 per cent. on the present nominal capital means very much more on the actual amount invested. To the United Telephone shareholders, in fact, it means 15 per cent. . . . With such a showing as this it is ridiculous to put forward the plea that the Company works under such peculiarly disadvantageous conditions in the metropolis that the present excessive charge for the service is justified, and that a reduction in the charge can only be made practicable if the Company is granted the statutory powers asked for in the Bill now before Parliament. In our view these additional powers should be withheld, at all events until the National Telephone Company has shown itself willing to deal more fairly by its metropolitan customers."

Electric Traction on the West Metropolitan Tramway System.—At the meeting of the West Metropolitan Tramway Company on Monday last, the Chairman remarked that he had once stated that two things were requisite to make the Company a success; the first was a double line, and the second was electric traction. They had commenced the double line, and as to the adoption of electricity, they had at last got the consent of the Local Authorities. The local authorities would not, however, either permit overhead wires or a "slot" in the road. He would be very glad indeed if the Lineff system could be adopted upon their line, but he would not risk a farthing of the shareholders' money in any experiment. If the Lineff Company liked to come forward and carry on the traffic at a less cost than by horse-power, they could. If anyone would only do the work for 4½d. per mile on the West Metropolitan system, he would hand the whole line over to them to work. The West Metropolitan Company could not afford to pay 9d. a mile; but if a company would do it for less it would be a different thing.

The Value of Useless Studies.—The following letter from Prof. G. F. Fitzgerald, which appeared in last week's *Nature*, will be read with interest:—

"It is rather surprising that Prof. Ayrton should indulge in covert sneers at Universities for devoting themselves to useless studies. It certainly ill becomes one whose life is bound up with electrical science, which is of such recent growth that nobody can pretend to forget how it owes its origin to those who studied it while useless. If Universities do not study useless subjects, who will? Once a subject becomes useful, it may very well be left to schools and technical colleges, to patent-mongers, and the trade. Mr. Bury is, on the other hand, mistaken in two respects. That a subject is useless is hardly worth considering as a recommendation for its being made *compulsory* on students. There are too many useless subjects for that. The great objection to compulsory Greek is that it is the principal stumbling-stone in the way of any literature being studied by ordinary University students. The Bible produced very little effect until it was read in translations; and the danger of a pagan revival, if ancient literature were studied without the obstruction of difficult languages, is the best reason for insisting on these languages in a Christian University. The second mistake of Mr. Bury is that it is any part of the business of a University to *teach*. Universities should certainly give facilities for students to *learn*. It is the business of the students to learn. If they are so ill prepared that they have not acquired the art of learning, they should go to a college or school or private teachers, and get taught; for teaching is the business of these institutions and persons. The business of Universities is to advance culture and knowledge, and to afford students an opportunity of learning how to do this. Prof. Ayrton, by omission, rather than by commission, seems utterly unable to appreciate the value of literature for its own sake. How can all this fierce toil he extols so justly advance a lot of savages?"

The Electric Railway Bills.—There is every appearance of considerable opposition to the several local railways which are being promoted in London. The petitioners praying to be heard against the Baker-street and Waterloo Railway include the trustees of the Constitutional Club, the National Liberal Club Buildings Company, the Gordon Hotels, the trustees of the County Fire Office and Provident Life Office, the Hotel Victoria, the vestry of the parish of St. Marylebone, the Society for Promoting Christian Knowledge, and Viscount Portman. Against the Central London Railway Extension Bill the Corporation of London and the London and North-Western Railway Company have presented petitions. Among the opponents praying to be heard against the City and South London Railway Extension Bill are the vestry of St. Mary, Islington, the Ecclesiastical Commissioners, the authorities of the Orphan Working School at Haverstock Hill, the trustees of the Stockwell Orphanage, and the Corporation of London. The Hampstead, St. Pancras, and Charing-cross Railway Bill is petitioned against by Messrs. Maple and Co., the Great Northern, London and North-Western, and Midland Railway companies, and the vestry of St. Marylebone. Mr. John Walter and the Corporation of London petition to be heard against the Waterloo and City Railway.—In the House of Commons on Tuesday evening Mr. Whitmore moved the appointment of a joint committee to consider the best method of dealing with the electric and cable railway schemes. The resolution was carried without opposition.

Aluminium Soldering.—The following methods of soldering aluminium are recommended by the Neuhausen Company. For sheet aluminium an iron-tin solder may be used with a flux composed of resin, neutral chloride of zinc, and grease. The metal should not be cleaned or scraped unless it is absolutely necessary to do so, in which case alcohol or essence of turpentine should be used for the purpose. For 5 per cent. aluminium bronze tin solder may be employed, but this is not possible with the 10 per cent. alloy, in which case the company recommends a preliminary copper plating. If it is difficult to dip the ends to be plated directly into the solution, pieces of blotting paper soaked in a solution of $CuSO_4$ may be laid on them, and a current passed. The flux mentioned above may be used. Another solder which is recommended is one consisting of copper 56 parts, zinc 46 parts, and tin 2 parts, applied with borax. Some tests made at Neuhausen showed that with these solders plates of aluminium soldered together edge to edge required a tractive effort of from 16½ to 18 tons per square inch to pull them asunder; if the edges overlapped 22¼ tons per square inch were required. Pieces of cast aluminium bronze, if placed in sand moulds, can be joined together autogenously by running in some of the molten metal. If this operation is properly carried out the joint is indistinguishable from the rest of the casting. Thin cylinders of aluminium are made in this way by bending the sheets round end to end, and soldering with molten aluminium.

Sunspots and Magnetic Disturbances.—In a recent communication to the *Comptes Rendus* (Vol. CXIV., No. 8) entitled "Note sur une tache solaire observée à l'Observatoire de Meudon du 5 au 17 Février courant," M. Janssen stated that with regard to the question of the relation between the phenomena of sunspots and terrestrial magnetic disturbances, he saw nothing in the facts hitherto brought to light to warrant the hypothesis of there being any correlation between them. However, as nothing ought to be rejected *a priori*, and as the study of the question could not but be advantageous to the progress of science, he would like to see meteorological and magnetic observatories multiplied on the surface of the earth, and particularly in the Southern hemisphere, so as to enable us to extricate, from amongst the magnetic and electric manifestations those which had a general and simultaneous character for an entire hemisphere; for it was evident that it was only phenomena of that order which could be attributed to solar action. With this view, M. Janssen would like M. Mascart to inquire of foreign meteorologists if, at the time of the fine aurora observed in America and Europe, and to which must be attributed the great magnetic disturbances recorded, anything of the same kind took place in the Southern hemisphere. Doubtless the Southern hemisphere, being before all things a watery one, auroral phenomena would be less frequent and intense than in our own, and moreover the observatories being further from the auroral regions, observations would be more difficult. Nevertheless, if it were thoroughly ascertained that nothing of the same kind took place at the same time in the Southern hemisphere, we should be in the possession of a fact which would render the theory of solar influence a very improbable one. In any case, M. Janssen was of opinion that it was by means of investigation and verifications of this description that we should succeed in solving the question, as yet so obscure, of the correlation between the accidents on the solar surface and terrestrial magnetic and electric phenomena.

ELECTROMAGNETIC THEORY.—XXV.

BY OLIVER HEAVISIDE.

(Continued from page 377.)

§ 122. The Hamiltonian vector ∇ occurs in all physical mathematics involving three dimensions, when treated vectorially. It is defined by

$$\nabla = \mathbf{i}\frac{d}{dx} + \mathbf{j}\frac{d}{dy} + \mathbf{k}\frac{d}{dz}, \quad . \quad . \quad . \quad . \quad (119)$$
$$= \mathbf{i}\nabla_1 + \mathbf{j}\nabla_2 + \mathbf{k}\nabla_3,$$

the second form being merely an equivalent one, often more convenient, and easier to set up. We see that the Hamiltonian is a fictitious vector, inasmuch as the tensors of its components are not magnitudes, but are differentiators. As, however, these differentiators are scalar—not scalar magnitudes, but scalar operators, having nothing vectorial about them—the Hamiltonian, in virtue of **i**, **j**, **k**, behaves just like any other vector, provided its differentiating functions are simultaneously attended to. Of course, an operand is always implied, which may be either scalar or vector.

The Hamiltonian has been called Nabla, from its alleged resemblance to an Assyrian harp—presumably, only the frame thereof is meant, without any means of evoking melody. On the other hand, that better known musical instrument, the Triangle, perhaps equally well resembles ∇, and it does not want strings to play upon.

First notice that

$$\mathbf{i}\nabla = \nabla_1, \qquad \mathbf{j}\nabla = \nabla_2, \qquad \mathbf{k}\nabla = \nabla_3, \quad . \quad . \quad (120)$$

and that these are all special cases of the scalar product

$$\mathbf{N}\nabla = \mathrm{N}_1\nabla_1 + \mathrm{N}_2\nabla_2 + \mathrm{N}_3\nabla_3, \quad . \quad : \quad . \quad (121)$$

where **N** is any unit vector. Here $\mathbf{N}\nabla$, or its equivalent Cartesian expansion, means differentiation with respect to length, say s, measured along the axis of **N**, usually denoted by

$$\frac{d}{ds} = l\frac{d}{dx} + m\frac{d}{dy} + n\frac{d}{dz}, \quad . \quad . \quad . \quad . \quad (122)$$

or by similar forms. This operation was termed by Maxwell differentiation with respect to an axis, which we may more conveniently call axial differentiation. We see, therefore, that $\mathbf{N}\nabla$, or the **N** component (scalar) of ∇, is an axial differentiator, the axis being that of **N**. Thus,

$$\mathbf{N}\nabla.\mathrm{P} = \frac{d\mathrm{P}}{ds}, \qquad \mathbf{N}\nabla.\mathbf{A} = \frac{d\mathbf{A}}{ds}, \quad . \quad . \quad (123)$$

P being scalar and **A** vector. Also

$$\mathbf{N}\nabla.\mathbf{AB} = \mathbf{A}.\mathbf{N}\nabla.\mathbf{B} + \mathbf{B}.\mathbf{N}\nabla.\mathbf{A}, \quad . \quad . \quad (124)$$
$$\mathbf{N}\nabla.\mathrm{V}\mathbf{AB} = \mathrm{V}(\mathbf{N}\nabla.\mathbf{A})\mathbf{B} + \mathrm{V}\mathbf{A}.\mathbf{N}\nabla.\mathbf{B}, \quad . \quad (125)$$

and so on, simply because $\mathbf{N}\nabla$ is a differentiator. Expanded in Cartesians, (124) contains the eighteen differential coefficients of the components of **A** and **B** with respect to x, y, and z. The last two equations will also serve to illustrate notation. The dots are merely put in to act as separators, and keep the proper symbols connected. Mere blank spacing would do, but would be troublesome to work. We may, however, use brackets equivalently.

Thus, $\mathbf{A}.\mathbf{N}\nabla.\mathbf{B}$ may be written $\mathbf{A}(\mathbf{N}\nabla)\mathbf{B}$, and this form may be used with advantage if found easier to read. Of course, $\mathbf{N}\nabla$ being scalar, on its insertion between the two members of **AB**, the result remains a scalar product. Similarly, $\mathrm{V}\mathbf{A}.\mathbf{N}\nabla.\mathbf{B}$, arising from $\mathrm{V}\mathbf{AB}$, is still a vector product.

A somewhat more general operator is $\mathbf{v}\nabla$, where **v** is any vector. It is plainly v times the corresponding axial differentiator, or $v.\mathbf{v}_1\nabla$. Thus, expanded,

$$\mathbf{v}\nabla.\mathbf{D} = (v_1\nabla_1 + v_2\nabla_2 + v_3\nabla_3)(\mathbf{i}\mathrm{D}_1 + \mathbf{j}\mathrm{D}_2 + \mathbf{k}\mathrm{D}_3), \quad . \quad (126)$$

which we may separate into **i**, **j**, **k** terms if we like.

When **v** is the velocity of moving matter, $\mathbf{v}\nabla$ comes frequently into use. Let, for example, w denote the measure of some property of the moving matter (here a scalar, but it may equally well be a vector), and, therefore, a function of position and of time. Its rate of change with the time at a *fixed* point in space is dw/dt, and the matter to which this refers is changing. But if we wish to know the rate of time-change of w for the *same* portion of matter, we must go thus. Let $\delta w/\delta t$ denote the result, then

$$\frac{\delta w}{\delta t} = \frac{dw}{dt} + \frac{dw}{dx}\frac{dx}{dt} + \frac{dw}{dy}\frac{dy}{dt} + \frac{dw}{dz}\frac{dz}{dt},$$

by elementary calculus. Or

$$\frac{\delta w}{\delta t} = \frac{dw}{dt} + \mathbf{v}\nabla.w, \quad . \quad . \quad . \quad . \quad (127)$$

where **v** is the velocity of the matter.

This is the equation extensively employed in hydrokinetics. In elastic solid theory the term $\mathbf{v}\nabla.w$ is generally omitted, being often small compared with the first term on the right. But, in special applications, it may happen that any one of the three terms in (127) vanishes. Thus the term on the left side obviously vanishes when w keeps the same in the same matter. If, however, for w we substitute a vector function, say **A**, even though it may not suffer change at first sight in the same matter, yet the rotational part of the motion will alter it by turning it round, so that $\delta\mathbf{A}/\delta t$ will not vanish.

The operator $\delta/\delta t$ is distributive, like d/dt and $\mathbf{v}\nabla$, as exemplified in (124), (125).

§ 123. If the moving matter is so connected that it moves as a rigid body, we have a further development. If we set a rigid body spinning about a fixed axis whose direction is defined by the unit vector $\mathbf{a}_1$, with angular speed a, the speed of any point P in the body equals the product of its perpendicular distance from the axis into the angular speed, and the direction of P's motion is perpendicular to the plane through the axis containing P. That is, a given particle describes a circle round the axis. This is obviously necessitated by the rigid connection of the parts of the body (or detached bodies). The velocity of P is therefore expressed by

$$\mathbf{v} = \mathrm{V}\mathbf{ar}, \quad . \quad . \quad . \quad . \quad . \quad (128)$$

if $\mathbf{a} = a\mathbf{a}_1$, and **r** is the vector to P from any point O on the axis. This is by the definition of a vector product.

Here we may observe a striking advantage possessed by the vectorial method. For (128), obtained by elementary considerations, proves without any more ado that angular velocities about different axes compound like displacements, translational velocities, or forces, or, in short, like *vectors*. Thus, in (128) we see that the velocity of P is the vector product of **a** and **r**. The latter fixes the position of P. The former depends on the spin, its tensor being the angular speed, and its direction that of the axis of spin. Now every vector, as before seen, may be expressed as the sum of others, according to the rule of vector addition. But every vector has its species. Thus, **r** being a vector distance, its components are vector distances. Similarly, **a** being a vector axis of spin with tensor equal to the angular speed, the components of **a**, for instance, the three terms on the right of

$$\mathbf{a} = \mathbf{i}a_1 + \mathbf{j}a_2 + \mathbf{k}a_3,$$

are vectors of the same nature. Therefore any spin may be replaced by other spins about other axes, according to the vector law. Of course the body cannot spin about more than one axis at once, but its motion is the same as if it could and did. This property is notoriously difficult to understand by Cartesian mathematics.

The most general kind of motion the rigid body can possess is obtained by imposing upon the rotational any translational velocity common to all parts. Let **q** be this translational velocity, then, instead of (128),

$$\mathbf{v} = \mathbf{q} + \mathrm{V}\mathbf{ar}. \quad . \quad . \quad . \quad . \quad . \quad (129)$$

Here observe that **q** is the velocity of the point O, or of any other point on the axis of rotation passing through the point O. We may infer from this that if we shift the origin O to Q, a point on a parallel axis, equation (129) will still be true, provided **r** means the vector from the new origin Q to P, and **q** means the translational velocity of Q itself. Of course, the

Digitized by Google

axis of rotation is now through Q. We may formally prove it thus. Take

$$\mathbf{r} = \mathbf{h} + \mathbf{R}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (130)$$

where **h** is the vector from O to Q and **R** the vector from Q to P. Put (130) in (129), then

$$\mathbf{v} = \mathbf{q} + \mathrm{V}\mathbf{a}\mathbf{h} + \mathrm{V}\mathbf{a}\mathbf{R}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (131)$$

But here $\mathbf{q} + \mathrm{V}\mathbf{a}\mathbf{h}$ is, by (129), the velocity of Q, say **u**, so we have

$$\mathbf{v} = \mathbf{u} + \mathrm{V}\mathbf{a}\mathbf{R}, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (132)$$

showing the velocity of P to be the sum of the translational velocity **u** at *any* point Q, plus the velocity at P due to rotation about the axis through Q.

All motion is relative. But observe the absolute character of the spin **a**. It is absolute just because it involves and depends entirely upon relative motions.

The translational velocity **u** of the point Q consists of a motion along the axis of rotation, combined with a transverse motion. The latter may be got rid of by shifting the axis. For if **w** is the velocity of Q transverse to the axis, if we go to the distance w/a from the axis through Q, keeping in the plane through the axis perpendicular to **w**, we shall reach a place where the velocity due to the rotation about the Q axis is either $+\mathbf{w}$ or $-\mathbf{w}$, according to which side of the Q axis we go. Choosing the latter, where the transverse motion is cancelled, and transferring the axis to it, we see that the general motion of a rigid body consists of a spin about a certain axis (which is termed the central axis), combined with a translation along this axis. That is, it is a screw motion. It may, however, be more convenient not to employ the screw motion with a shifting axis, but to use (132), and let **u** and **a** be the translational and rotational velocities of a point Q fixed in the body.

We may also have simultaneous spins about axes which do not meet. Thus, let **R** be the vector from any origin O to a point Q about which there is a spin **a**, and **r** the vector from O to any other point P. Then the velocity of P due to the spin is, by the preceding,

$$\mathbf{v} = \mathrm{V}\mathbf{a}(\mathbf{r} - \mathbf{R}). \quad . \quad . \quad . \quad . \quad . \quad . \quad (133)$$

Next let there be any number of points of the type Q, each with its spin vector **a**. The velocity at P is then the sum of terms of the type (133), in which **r** is the same for all. The result is therefore

$$\mathbf{v} = \mathrm{V}\mathbf{A}\mathbf{r} - \Sigma\,\mathrm{V}\mathbf{a}\mathbf{R}, \quad . \quad . \quad . \quad . \quad (134)$$

where **A** is the sum of the **a**'s, or *the* spin of the body, whilst the *minus* summation expresses the velocity at O. For example, two equal spins, **a**, in opposite senses about parallel axes at distance h combine to make a mere translational velocity perpendicular to the plane of the axes; speed ah. I give these examples, in passing, to illustrate the working of vectors. These transformations are effected with a facility and a simplicity of ideas which put to shame the Cartesian processes. It may, indeed, be regarded as indicative of a mental deficiency to be unable to readily work the Cartesian processes—which is in fact my own case. But that does not alter the fact that if a man is not skilful in Cartesians, he may get along very well in vectors, and that the skilful mathematician who can play with Cartesians of great complexity, could as easily do far more difficult work in vectors, if he would only get over the elements, and accustom himself to the vectors as he had to do to the other method.

§ **124.** Going back to (127), we should, when the property whose time-variation is followed belongs to matter moving as a rigid body, employ in it the special reckoning of **v** of equation (132), giving the velocity of any point P in terms of **u** and **a** at an invariable point Q in the body. Thus, we have

$$\frac{dw}{dt} = \frac{\delta w}{\delta t} - (\mathbf{u} + \mathrm{V}\mathbf{a}\mathbf{R})\nabla.w. \quad . \quad . \quad . \quad (135)$$

But equation (127) applies not merely to the case of matter moving through space, carrying some property with it, but also when the matter itself is fixed, whilst some measurable property or quality moves through the matter, or is transferred from one part of the matter to another. And here we may leave out the consideration of matter altogether, and think only of some stationary medium which can support and through which the phenomenon can be transferred.

Thus, we may have a system of electric displacement **D** in a dielectric, which may be moving through it independently of any motion it may possess, and apply (127) to calculate $\dot{\mathbf{D}}$. It is, however, only in relatively simple cases that this can be followed up. For it is implied that we know the motion of the displacement and how it changes in itself, and these may be things to be found out.

But should the displacement system move as a rigid body, the matter is greatly simplified. This will occur when the sources of the displacement (electrification, for instance) move as a rigid body, and the motion is of a steady type, so long continued that the displacement itself (in the moving system) is steady. Writing **D** for w in (135), we shall have

$$\frac{d\mathbf{D}}{dt} = \mathrm{V}\mathbf{a}\mathbf{D} - (\mathbf{u} + \mathrm{V}\mathbf{a}\mathbf{R})\nabla.\mathbf{D} \quad . \quad . \quad . \quad . \quad (136)$$

Here $\mathrm{V}\mathbf{a}\mathbf{D}$ is the rate of time-variation of the displacement in a moving element of the displacement system, caused by the rotation. It is zero when the displacement is parallel to the axis of spin, and a maximum when it points straight away from the axis, like the spoke of a wheel.

The displacement system is, however, not necessarily or usually the same when in steady motion as when at rest. In the latter case only can it be regarded as known initially. Set it steadily moving and it will (by reason of the self-induction) be changed to another displacement system. Nevertheless (136), along with the electromagnetic equations, enable us to find the new displacement system.

Should, however, the velocities of the connected sources be only a very small fraction of the speed of propagation of disturbances through the medium, the re-adjustment of the displacement as the sources move takes place practically instantaneously (as if the speed of propagation were infinite), so that the displacement system remains unchanged, preserving its stationary type, whilst it moves through the medium as a rigid body, in rigid connection with the sources. (This is obviously quite incorrect at a great distance from the sources, but there the effects themselves are insensible.) In this case, too, it is clearly unnecessary that the motion of the sources should be steady. Thus, in (136), **D** becomes the known displacement system (of equilibrium), moving as defined by **u** and **a**, which may vary anyhow.

Similar considerations apply to systems of induction, moving with their sources. A general caution, however, is necessary when there are conductors or other bodies in the field, not containing sources. To keep them from having currents induced in them, or in other ways upsetting the regularity of the moving system, they should also partake in the motion, by rigid connection.

§ **125.** Equation (136) also applies to the motion through a medium of a "strain-figure," treated of by Dr. C. V. Burton in the current number of the *Phil. Mag.* (February, 1892). It is similar to that of slow motion of an electrical displacement system. Imagine a stationary infinite elastic medium with inertia, somehow set into a strained state, and let the speed of propagation of disturbances of strain be practically infinite. If then the strain-figure can move about through the medium, it will do so as a rigid body, provided the sources of the strain do so. In the above, **D** may signify the displacement (ordinary), whose variation in space constitutes the strain. Then $\dot{\mathbf{D}}$ is the velocity of displacement, and is expressed in terms of the velocity of the strain-figure. From the expression for the kinetic energy of the complete strain-figure, the mechanical forces concerned can be deduced. As this is to be done on dynamical principles involving Newton's laws, we may expect beforehand that a strain-figure symmetrical with respect to a centre will behave as a Newtonian point mass; as does a similar electrical displacement figure. But, in general, without symmetry, the calculation of the forces concerned would be very troublesome indeed.

But the real difficulty appears to me to be rather of a physical than a mathematical nature. We have first to get some idea of how the strain-figure is kept up. Let it be

Digitized by Google

stationary first. Then the strain-figure is referred to a forced or unnatural state of the medium in certain places. At any rate, we require intrinsic "sources" somewhere, and perhaps it might for this reason be convenient to consider these portions of the medium (with the sources) to constitute the atom or molecule, rather than the whole strain-figure.

Now, having got a stationary strain-figure, how is it to be set moving? Three ways suggest themselves. First, a bodily motion of the medium carrying the strain-figure with it. This is plainly inadmissible. Next a motion of the atomic portions only of the medium (with the sources) through the rest of the medium, either disturbing it to some extent near by, or not disturbing it at all—slipping through, so to speak. This would carry on the strain-figure. But it is inadmissible, if it be our object not to move the medium at all in any part. Thirdly, we may keep the whole medium at rest, and cause the sources themselves to move through it, so that the atomic portions of the medium change. But there is no means for doing this presented to our consideration. It lies beyond the dynamical question of the forces on an atom brought into play if the strain-figure can move in the manner supposed. The second course above, on the other hand, is more intelligible, although it implies something akin to liquidity.

These objections are, however, only made suggestively. The matter is sufficiently important to be deserving of a thorough threshing out.

(To be continued.)

HERTZ OSCILLATIONS.*

BY A. PEROT.

In a recent article† M. V. Bjerknes has shown that the oscillations of electromotive force produced in the neighbourhood of conducting wires by Hertz's method could be represented by the expression

$$Y = A e^{-a(t-\phi)} \sin \pi \left(\frac{t}{\tau} - \phi\right).$$

I propose to carry out similar investigations in the case of an excitation different to that employed by M. Bjerknes, namely, that used by M. Blondlot‡ in his recent researches, slightly modifying it. In the apparatus which I used the oscillations were propagated through the wires of a *completely closed* circuit, comprising the following parts:—The region where the oscillations originated, a copper wire about 8m. long stretched horizontally; a movable bridge, connecting this wire to another one stretched parallel to it at a distance of 10cm.; a fine stretched iron wire, about 80m. long, connected this second copper wire to the spot where the oscillations were produced. In this way the opposite waves of E.M.F. given out by the exciter were propagated in either direction through this circuit, and interfered in the iron wire and not in the copper wires, owing, firstly, to the rapid damping of the oscillations, and, secondly, to the diminution of strength with the distance traversed. Two opposite points, A and B, of the line were connected to the two terminals of a spark micrometer, giving the 500th of a millimetre.

With things arranged in this manner, the bridge being in any position, and the micrometer not sparking, I moved the point so as to obtain a continuous flow of sparks. The sparking distance measures, under these conditions, according to Warren de la Rue and Müller, the square of the maximum difference of potential between the points A and B. Varying the position of the bridge, we were able to see that this sparking distance d varied with the distance a of the points A and B measured along the wires of the circuit. We could, therefore, construct the curve $d = f(a)$ point by point.

The figure shows one of these curves.

I obtained seven of these curves with different exciters, the maxima and minima of d for each of them are contained in the following table:—

Curves.	a.			λ
	1st Maximum.	2nd Minimum.	2nd Maximum.	
1	470 cm.	950 cm.	...	950 cm.
2	470 „	960 „	1,440 cm.	960 „
3	470 „	940 „	1,400 „	940 „
4	580 „	1,140 „	...	1,150 „
5	640 „	1,320 „	...	1,300 „
6	960 „	...	...	1,920 „
7	1,100 „	...	...	2,200 „

The curve has a very regular appearance, and presents decreasing maxima and increasing minima. The distances from the origin (first minimum) to the first maximum, and from one maximum to the second minimum, are equal. Hence, if we assume the electromotive forces Y_1 at B and Y_2 at A, given by the equations

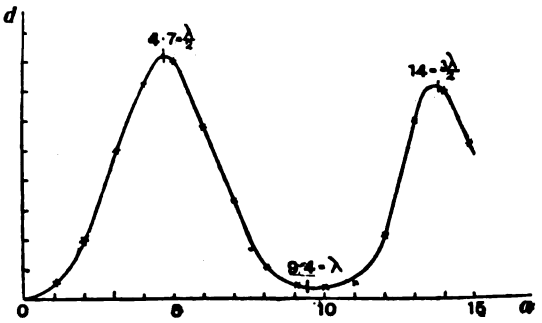
$$Y_1 = \phi(t) = C e^{-at} \sin 2\pi \frac{t}{\tau},$$

$$Y_2 = \phi\left(t + \frac{a}{V}\right),$$

and d proportional to the maximum value of $(Y_1 - Y_2)^2$, it is easy to construct the curve $d = f(a)$, which presents equidistant maxima and minima, the respective values of which are

$$D\left(1 + e^{-\frac{2n+1}{2} a\tau}\right), D\left(1 - e^{n a \tau}\right),$$

n being a whole number.



The calculated curve does not differ sensibly from the observed curve; and it is worthy of notice that the values of the logarithmic decrement $a\tau$, deduced from the comparison of the minimum and of the two maxima are, ·49 and ·46. The proposed formula, therefore, well represents the experiment. The electromotive force is of the order of a *simple damped pendulum*, and does not correspond to a complex sound. The damping is, moreover, very rapid. During the fourth period the electromotive force is only one-tenth of what it was at the commencement.

With this apparatus is it possible to excite a resonator and to measure its wave length? The experiment, which is in the affirmative on all points, is worth describing, the conditions being different to those under which M. Blondlot worked. The waves traversed the two-line wires in opposite directions, acting on the resonator at very different instants of time and in a very unequal manner, owing to the presence of the 80m. wire, which formed a sort of lateral loop. I was able with exciters, giving wave-lengths of 22m. to 13m., to excite a resonator and to measure its wave-length. The numbers found, 8·6m. and 8·3m., are identical to within ·035. I have even in the course of other researches been able to excite a resonator for which $\lambda = 1{\cdot}9$m., by an exciter, the wave length of which was about 30m.

In these experiments it is impossible, I think, to explain the phenomenon of *multiple resonance* otherwise than M. Poincaré* conceived it and MM. Bjerknes and M. Blondlot assumed it.

METRIC WEIGHTS AND MEASURES.

BY J. EMERSON DOWSON.

It is no doubt pleasant to be amused, either in a Royal Institution lecture, or in a Note in *The Electrician*, even at the expense of one's convictions; and it seems to me a point in favour of the metric system that it can lend itself to such treatment. At the same time there is a serious side to the question, and as prominence has recently been given to Mr. Coleman Sellers's view of the subject, I crave leave to state briefly the reasons for adopting the metric weights and measures in this country.

In your Note it is stated, "We are constantly being told that some semi-barbarous country has adopted the metric system, among other fashions of civilization; and that this market or that will only purchase stove pipes that will fit a metrically designed stove, or hat bands a certain number of centimetres in depth." In reply, I think I cannot do better than give the following list, up to date, of the countries actually using the metric weights and measures:—

Country.	Population.	Country.	Population.
Norway and Sweden..	6,774,409	Austrian Territories...	41,827,700
Denmark and Iceland..	2,244,650	Greece	2,187,208
Danish West Indies ...	33,763	Roumania	5,376,000
Germany.....	46,855,704	Turkey (in Europe)...	4.668,000
Holland	4,450,870	Mexico	10,447,974
Java, &c.....	28,500,000	Central America	3,053,000
Belgium	6,030,043	Haiti	550,000
France	38,218,903	Colombia (Republic)...	3,500,000
Algeria	3,817,460	Venezuela	2,121,988
Senegambia	1,000,000	Ecuador.....	1,000,000
Portugal..	4,306,554	Brazil	14,000,000
Azores and Madeira ...	401,624	Uruguay	700,000
Spain—		Argentine Republic ...	4,200,000
Canary Islands.....		Chili	2,665,926
Fernando Po.....	17,550,216	Peru	2,970,000
West India Islands.		Japan.....	34,338,000
Philippine Islands..			
Italy	29,699,781	Total	323,489,773

It must be admitted that in this total population of over 323 millions the proportion of semi-barbarians is small, unless we are to include under this denomination all those nations which have shewn themselves in advance of ourselves by adopting the metric system introduced by France.

In Russia there is a strong disposition to adopt the metric system, and the Government has already decided to begin in certain directions. In Finland it has been compulsory since the beginning of this year. Col. Howard Vincent, M.P., has just visited China, and reports that "a recommendation is about to go forward from a high authority, to whom attention is paid, that China should adopt, as Japan has already done, the metric system of measurement of France and Germany."

The question of adopting the metric weights and measures in the United States is also receiving serious attention, and in July, 1890, the President transmitted to Congress a letter from Secretary Blaine, accompanied by a Report on Weights and Measures, unanimously adopted by the International American Conference. Mr. Blaine in his letter says:—

"This Report recommends the adoption by the United States of the Metrical Decimal System of Weights and Measures, which is now in use by the Governments and people of all the other American Republics and most of the nations of Europe, and which is already authorised by the laws of the United States. The adoption of this system in the Customs' service would, it is believed, greatly promote the public convenience."

We see then that at the present time all the leading countries of the world, except Russia and those where the English language is spoken, have already adopted the metric system, and that in Russia and the United States the question is being seriously considered. It would certainly be adopted at once in those countries if England were to adopt it.

We are, therefore, within measurable distance of having an international system of weights and measures, if only England will take the necessary step, and no one can dispute the advantage this would be to all concerned. It may, however, be said that this is only the dream of the impetuous reformer, and that we can well afford to stand aloof, or be left severely alone. I will endeavour to show that from a commercial point of view such a policy of isolation would be suicidal, and even at the present time I believe it to be prejudicial. Foreign buyers naturally prefer to deal in weights and measures they are familiar with, rather than be perplexed and worried by such arbitrary and complicated odds and ends as are used in this country. We have already seen that a large proportion of the nations with whom it is our interest to trade, *e.g.*, all the States of South America, now use the metric weights and measures. On the other hand, the manufacturers of France and Germany, to say nothing of Belgium, Italy, &c., all use the metric system also, and are therefore able to offer goods and machines which, without extra trouble or expense, have been made according to the metric weights and measures, and on this account we are gradually being placed at a disadvantage. Formerly we had a greater command over foreign markets than at present, but of late years most of the European countries have increased their powers of production, and are now energetically pushing the sale of their wares abroad. Germany especially is unceasing in her efforts to compete with us, and the fact that she and the other countries referred to use weights and measures which nearly all foreign buyers now prefer, gives them an advantage we can ill afford to allow.

I will give some authorities for these statements. The Foreign Office Report No. 180, dated 1st August, 1890, on subjects of general interest in Italy, says:—

"Manufacturers state that the exertions of German travellers to push their trade are indefatigable, and, as they are always anxious to comply with the desires of their customers, they are often successful, while British firms, instead of travellers, forward catalogues, which are of little or no use, especially as they are for the most part drawn up in English, and *prices are quoted in English weights and measures.*"

In the British Consular Report on the trade of Japan, No. 922, of July last, it is pointed out that preference is now given to manufacturers of machines and materials who use the metric system. This is confirmed by Col. Howard Vincent, in his recent report addressed to the Master Cutler of Sheffield. He says:—

"The Director of the Imperial Japanese Artillery (Lieut.-Col. T. Ota), an experienced officer with European training, expressed himself as fully sensible of the excellence of the metal manufactures of Sheffield, and of their superiority in cost, quality, workmanship, and originality of design. Notwithstanding these advantages, he considered it so easy for mistakes to be made in the measurements by feet and inches that, when exact dimensions were important, his Government preferred to order their material from Creuzot in France and Krupp in Germany, where the metric system is used, so that they may be relieved of trouble and anxiety."

In December last the Consul-General for Peru in London gave public notice that in future it would be necessary to comply with the following regulations in making out consular invoices:—

"In invoices of articles made of cotton, wool, linen, or silk, the length of each piece contained in the packages must be given in metres. In all cases the weight in kilograms must be declared on the invoice."

In September last the British Vice-Consul at Alexandria reported that:—

"The English technical terms, weights and measures, were utterly unintelligible to a large proportion of the persons to whom merchants in this country forward their circulars and price lists."

He strongly advised English export houses to use the metric system, and to adjust their quotations to the requirements of Egyptian customers.

In speaking of the importance of adopting the metric weights and measures for goods exported to Mexico and to Central America, an able writer in the *Engineering and Mining Journal* of New York shrewdly remarks that the goods sent to these countries should be made in sizes and shapes the buyers are accustomed to, and he adds, "If we are going to contest with England the commercial control of this hemisphere, why should we not take advantage of her obstinacy, and, by suiting her customers, get them away from her?"

Much more might be said in favour of the adoption of the metric weights and measures in this country. To keep within the limits of a short article I have merely touched on

Digitized by Google

the commercial and practical side of the question, and from this point of view alone, I think it must be conceded that no such narrow issue is involved as is inferred in the reference to "stove pipes and hat-bands." When a deputation of the Decimal Association waited on the Chancellor of the Exchequer in May last, Sir Wm. Thomson, who was one of the speakers, remarked that "a large part of the time and work in an engineer's office is devoted to calculations that would be unnecessary and that would be much simplified if we had the metric system." Many ingenious proposals have been made for decimalising some of our existing weights and measures; and doubtless some of them would greatly improve those now in use; but I entirely agree with the Select Committee of 1862 that "it would involve almost as much difficulty to create a special decimal system of our own, as simply to adopt the metric decimal system in common with other nations. And if we did so create a special national system, we should, in all likelihood, have to change it again in a few years, as the commerce and intercourse between nations increased, into an international one." An ideal best is not possible; but next to this, the metric system certainly presents the greatest advantages and the fewest drawbacks, from many points of view.

I have not touched on the importance of the educational question involved, as this may not be considered within the province of a technical journal, such as *The Electrician*. I may, however, add that the Education Department has now fully recognised the need of giving instruction in the metric system, and the code issued last year provides that the principles of this system shall be taught in Standards V., VI. and VII. of the Primary Schools.

OBSERVATIONS OF ATMOSPHERIC ELECTRICITY FROM A CAPTIVE BALLOON.*

BY E. SEMMOLA.

These observations were made at Naples by means of the captive balloon *Uronia*. A vertical bar of brass half a metre long, terminated at the top by a brass disc 28cms. in diameter, was fixed to the car by a strong insulator. This disc communicated by means of a copper wire with the gold leaf of a dry battery electroscope placed in the car at about the same level. To this brass bar the upper end of a 2mm. copper conductor (*corde*) was soldered at several points, the conductor being enclosed within a double insulating covering—an inside one of india-rubber, an outside one of cotton. This conductor, 280m. in length, came down from the balloon and was arranged in long zigzags on a floor close to the ground; it was connected at the far end to a second dry battery electroscope. To avoid friction it was thought better to arrange the conductor in this manner than to wind it round a drum with a metal axis.

The day was calm and clear. At 9 a.m. the balloon ascended, carrying the conductor up with it, and in two minutes it reached an elevation of 280 metres, where it was maintained. During the ascent the gold leaf of the upper electroscope and that of the lower deflected towards the negative poles, both indicating, therefore, positive electricity; the deflection of the lower electroscope was, however, much the greater. A few seconds after the departure the gold leaf of the lower electroscope kept striking against the negative pole of the battery, and on being detached it immediately came into contact with it again. When the *Uronia* stopped at 280 metres elevation, the lower end of the copper conductor was put to earth, the observers in the car being warned by a whistle from the boiler of the traction locomotive. *Immediately after the whistle* the gold leaf of the lower electroscope remained vertical, and that of the upper electroscope turned *in a marked manner* towards the positive pole, indicating, therefore, negative electricity. When the earth communication was broken the lower gold leaf again deflected violently towards the negative pole, and that of the upper electroscope began once more to deflect slightly towards the negative pole. This observation was repeated several times and always with the same results.

On another occasion the lower end of the conductor was connected to a Palmieri electrometer. While the balloon was ascending the electrometer showed a uniform and regularly increasing deflection. At the elevation of 280m. the needle pointed to 50deg. As soon as the conductor was put to earth the needle went back to 0deg. The earth connection being broken, the needle deflected with a violent rush through an angle of more than 70deg.

This method allows us to discover the electric condition of the conductor at either end, and in this way to make simultaneous observations. Up till now observers have worked with a free balloon, or, remaining on the earth, have made use of a captive balloon, to take up a hanging copper conductor from the ground, where it was connected to an electrometer. In the latter case there were always indications of positive electricity. With a free balloon, carrying in the car all the apparatus which was thus insulated in space, the electricity observed was negative. This was the case in the memorable aerial voyage of Gay-Lussac and Biot, and in the ascent of the engineer Marcillac in 1886.

The method of simultaneous observations, using a captive balloon, should doubtless give better results than any obtained with the free balloon, which, in its rapid journey, at one time ascending, at another descending, continually changes the conditions, and can only yield complex and uncertain results, difficult to discuss.

* *Comptes Rendus*, Vol. CXIV., No. 7.

MEETINGS OF SCIENTIFIC SOCIETIES, &c.

(TO-NIGHT) FRIDAY, March 4th.

ELECTRO-HARMONIC SOCIETY.

8 p.m. Ladies' Night. Concert at St. James's Hall Restaurant.

ROYAL INSTITUTION.

9 p.m. Evening Discourse: "The Surface-Film of Water, and its Relation to the Life of Plants and Animals." By Prof. L. C. Miall, F.L.S.

SATURDAY, March 5th.

ROYAL INSTITUTION.

3 p.m. Afternoon Lecture: "Matter at Rest and in Motion. By Lord Rayleigh, F.R.S.

MONDAY, March 7th.

ROYAL INSTITUTION.

5 p.m. General Monthly Meeting.

SOCIETY OF ENGINEERS.

7:30 p.m. Ordinary Meeting. Paper to be read on "Electrical Traction and its Financial Aspect." By Stephen Sellon.

SOCIETY OF ARTS.

8 p.m. Cantor Lecture. III.—2. "The Uses of Petroleum in Prime Movers." By Prof. William Robinson, Assoc. M.Inst.C.E.

TUESDAY, March 8th.

INSTITUTION OF CIVIL ENGINEERS.

8 p.m. Ordinary Meeting. Paper to be read with a view to discussion: "Petroleum Engines." By Prof. W. Cawthorne Unwin, F.R.S.

WEDNESDAY, March 9th.

HIGH-PRESSURE DISCHARGES.

While the intelligent public are still asking whether NIKOLA TESLA's lamps are ready for practical use, and while not a few householders are hesitating to wire their houses because they understand that the time is at hand when wires will be no longer needed, Prof. ELIHU THOMSON has turned his attention to the fascinating study of high-pressure discharges. An article in the *Electrical World* of New York, an abstract of which will be found elsewhere, describes a few of his experiments, and clearly sets forth the apparatus which has been employed. Prof. THOMSON has connected a large induction coil or transformer to an ordinary alternating-current supply circuit with 100 volts, and with a frequency of 125 or 250. This transformer apparently presented no special features, and yielded 10,000 to 12,000 volts, giving a half-inch spark. A condenser was connected across this secondary circuit, and this too seems to call for no remark. The large induction coil shown at the Paris Electrical Exhibition in 1881 was excited by an alternate-current dynamo; but induction coils have always been very uncertain in their behaviour, refusing to work at times with all the obstinacy of a HOLTZ machine, and too often the cause has been a complete breakdown of the insulation. Now that the art of insulation is much better carried out in commercial transformers than was ever thought of by the instrument makers who made large induction coils, there is little difficulty in providing 10,000 volts for experimental purposes. Prof. THOMSON connects in the secondary circuit another induction coil of a few turns. The primary consists of 15 to 20 convolutions of wire, and the secondary of 150 turns of fine silk-covered wire in one layer. It is needless to say that this coil is immersed in oil.

Digitized by Google

On oil insulation must depend the success of all experiments such as those of Mr. Tesla, or of Prof. Elihu Thomson; and if only some solid insulating compound could be found which would not be acted upon by oil it is probable that all transformers would soon be enclosed in oil tanks. Those used at the Lauffen-Frankfort transmission experiments were so enclosed, and this system of insulation has been adopted in many other cases. The original Brooks system of oil insulation consisted in a serving of jute, which sufficed to keep the conductor away from the iron pipe in which it was enclosed, and in the use of mineral oil as the real insulator. The idea is very old, and was recommended by Mr. Lane Fox in the patent which has been the subject of so much argument before Mr. Justice Smith during the present week. Mr. Tesla uses linseed oil, and finds that it has a slow but definite action on gutta-percha. Prof. Elihu Thomson uses a silk covering for the wire, and a silk thread between the adjacent turns. Oil insulation will probably play an important part in the electrical engineering of the future, and it seems that little remains to be done to bring it into a practical form for even the highest pressure.

One of the features of the experiment with high potential discharges is the sparking distance of the secondary or tertiary circuit, and it is by this distance that the actual voltage may be guessed at. Unfortunately, the experiments which have been made on sparking distances have, with but a solitary exception, been made under purely laboratory conditions. That a ball, a disc and a point, carefully cleaned between each discharge, should be taken as a starting point in such an investigation is very proper; and this subject may be said to be fairly established now that Messrs. Siemens Bros. have succeeded in repeating Mr. De La Rue's experiments with close exactness. But under no cases but those of laboratory apparatus can the terminals of the spark gap remain clean, and under no conditions but those of laboratory experiments will these terminals be carefully cleaned after each discharge. In the design of lightning arresters on the evidence of such experiments, it is necessary to allow a very large factor of safety; for after a few months the points will become dirty, and the voltage required to produce a spark will probably be largely reduced. Spark distances with clean terminals tell us more about the dielectric properties of air than anything else, and from such experiments some very interesting purely scientific knowledge may no doubt be forthcoming. But for practical purposes, and for industrial and engineering applications of these high pressures, sparking distances must be studied under working conditions. Mr. Ferranti has made such experiments, and some of the results have been recorded in our columns. He found that after the lapse of one or even two minutes. a discharge might take place without any alteration in the pressure or the distance between the terminals. It is not possible that the air itself could gradually break down as a solid might, and it is unlikely that minute dust particles could form a bridge, as happens sometimes in oil. It is probable that a brush discharge oxidizes or even partly volatilizes the terminals, and may slightly heat the air, and that these circumstances facilitate the discharge. These conditions require further investigation, they are already of considerable importance in connection with electrostatic measuring instruments. Brilliant and interesting as the recent work of J. J. Thomson, Tesla, and Elihu Thomson have been, one of the firstfruits of the study of high-pressure induction discharges ought to be a more accurate knowledge of sparking distances under practical conditions; for it is not until this is established that any useful applications of this branch of electricity can be hoped for.

NOTES ON SUBMARINE CABLE WORK.

BY H. D. WILKINSON.

(*Continued from page 401.*)

2. The Mark Buoy.—The ship generally manages to reach the position of the fault some time in the morning, so as to get an altitude for the longitude of the position. A sounding is also taken, and the latitude is ascertained at noon. A steel mark buoy, such as shown in Fig. 6, and weighing about 18cwt., is then moored as nearly as possible over the position of the cable to act as a guide while grappling, and as a bearing to go by when the cable is hooked. The buoy is moored by means of a 3cwt. mushroom anchor (Fig. 7), this particular form of anchor having been found to hold well in almost any kind of bottom, and having no projecting points or arms, as in the ordinary anchor, which might foul with or chafe against the cable. This anchor is usually shackled to 15 fathoms of heavy chain ($\frac{7}{8}$in.) and the buoy rope attached to the end of the chain. The buoy rope is paid out till the

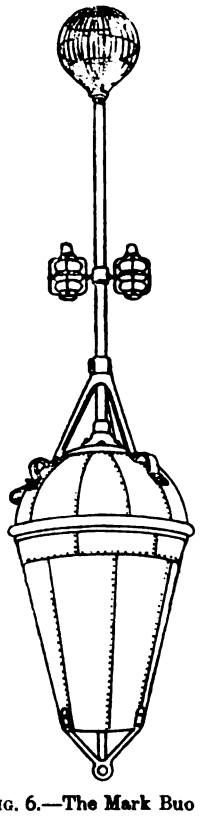

Fig. 6.—The Mark Buo

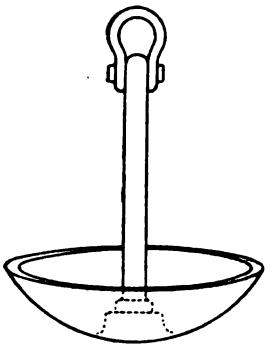

Fig. 7.—Mushroom Anchor.

anchor is within a few fathoms of the bottom, the end being then attached to the buoy chain on board. The bight is then thrown overboard and the buoy slipped, the slack chain allowing the anchor to reach bottom, and hold there. In deep water, for lightness, the buoy rope is of manilla, but as chafing is likely to occur on the bottom, it is customary to put in a length of 100 fathoms or more of compound steel wire rope. This is made with three cable-laid strands, each containing three steel wires, served with tarred manilla yarn, and known as 3 × 3 buoy rope. A length is also put in between the buoy chain and manilla rope, and in shallow water the compound rope is used throughout the whole length. The idea is, of course, to provide weight enough below to bed the anchor, and strength of rope sufficient to resist chafing, while at the same time lightness is a consideration, so as not to sink the buoy too far. If much overweighted, the buoy rapidly sinks; and buoys have been recovered from great depths where the enormous pressure of the water has entirely collapsed them. The buoy chain ($\frac{3}{4}$in.) is much lighter than the anchor chain. To the top of the buoy is riveted a holder for the beacon or flagstaff. During operations at night it is customary to lower a boat with hands

Digitized by Google

to light the lamps on the buoy. As a boat fender the buoy is usually fitted with a belt of stout rope or packing a little above the water line.

3. Grappling.—The ship now leaves the buoy, and steams out about a mile, in a course at right angles to the line of cable, then lowers grapnel and steams back slowly up to cable, crossing

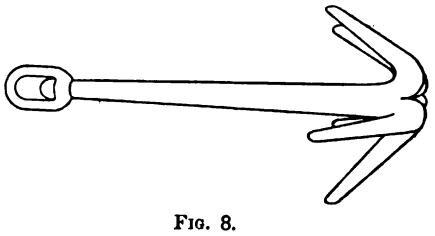

FIG. 8.

and recrossing it till hooked. The speed for grappling is about one or two knots an hour according to the bottom, and is slowest for a rocky bottom. Cable ships generally carry various kinds of grapnel to suit different conditions of bottom met with. The old form of 5 or 6-prong grapnel (Fig. 8) is still a very effectual grapnel for bottoms of a soft nature, such as sand or

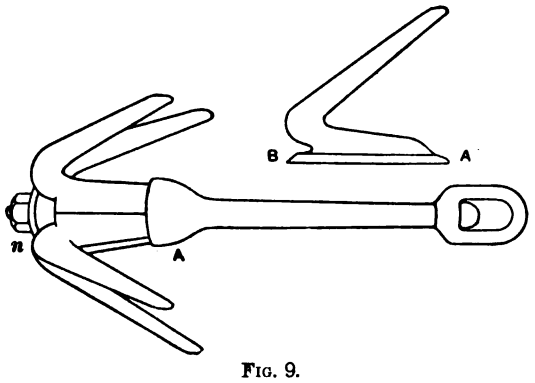

FIG. 9.

ooze; but meeting with any hard obstruction, such as rock, the prongs bend down or break off. To retain the use of the shank of the grapnel while the prongs are bent or broken off, many forms of grapnel with removable prongs have been devised. In one of these (Fig. 9), made by the Telegraph Construction and Maintenance Company, the prongs fit into a

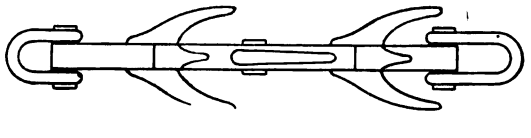

FIG. 9A.—Sliding Prong Centipede Grapnel.

hollow boss on the shank at A, and the ends at B are all enclosed by a collar and firmly fixed in position by the nut *n*. Another form, constructed by Messrs. Johnson and Phillips, is the sliding prong grapnel, and is provided with removable cast steel prongs of the kind shown in Fig. 9A. By taking the shackle off one end, the broken prongs may be slipped off and

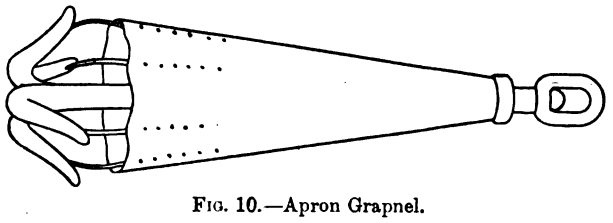

FIG. 10.—Apron Grapnel.

renewed. For rocky bottoms the Dutton apron grapnel (Fig. 10) is frequently used. In this grapnel the apron forms a guard for the prongs against breakage by rocks, and the opening between the prongs and the lower edge of the apron is only a little larger than required for the cable to enter. There are also retaining springs from the apron to the prongs. The grapnel in Fig. 11 has a guard for the same purpose, made of four wrought-iron arms. These guards prevent the cable getting out of the grapnel when it is jumping over uneven ground. The first form of this kind of grapnel was used in the "Great Eastern" when grappling for the lost end of the '65 Atlantic cable. This was made by lashing five

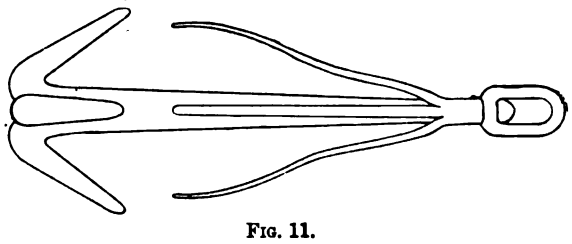

FIG. 11.

bent steel springs, about 1¼in. wide by $\frac{3}{16}$in. thick, to the stem of the grapnel, as shown (Fig. 11A). It will be remembered that the "Great Eastern," under the command of Captain (now Sir James) Anderson, laid the '65 Atlantic cable from Ireland towards Newfoundland, and that when about 1,180 miles from Valentia an electrical fault developed in the cable. In attempting to pick up and remove this fault the cable parted, the end

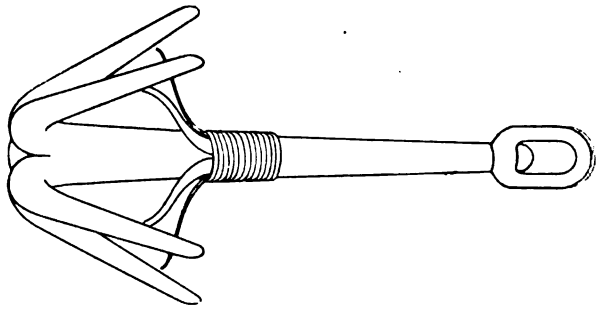

FIG. 11A.—Atlantic Cable Grapnel.

going overboard in 1,950 fathoms. This occurred on August 2nd of that year, and all attempts then made to recover it were ineffectual. But the "Great Eastern" returned in the following year, and, after successfully laying the '66 cable, went back to the position where the end of the former cable had been lost, and eventually raised the end, with the grapnel described, on September 2nd, completing the cable to Newfoundland in six days from that date. This was the first occasion on which a cable had been raised from a depth exceeding 500 fathoms.

(To be continued.)

CRYSTAL PALACE ELECTRICAL EXHIBITION.

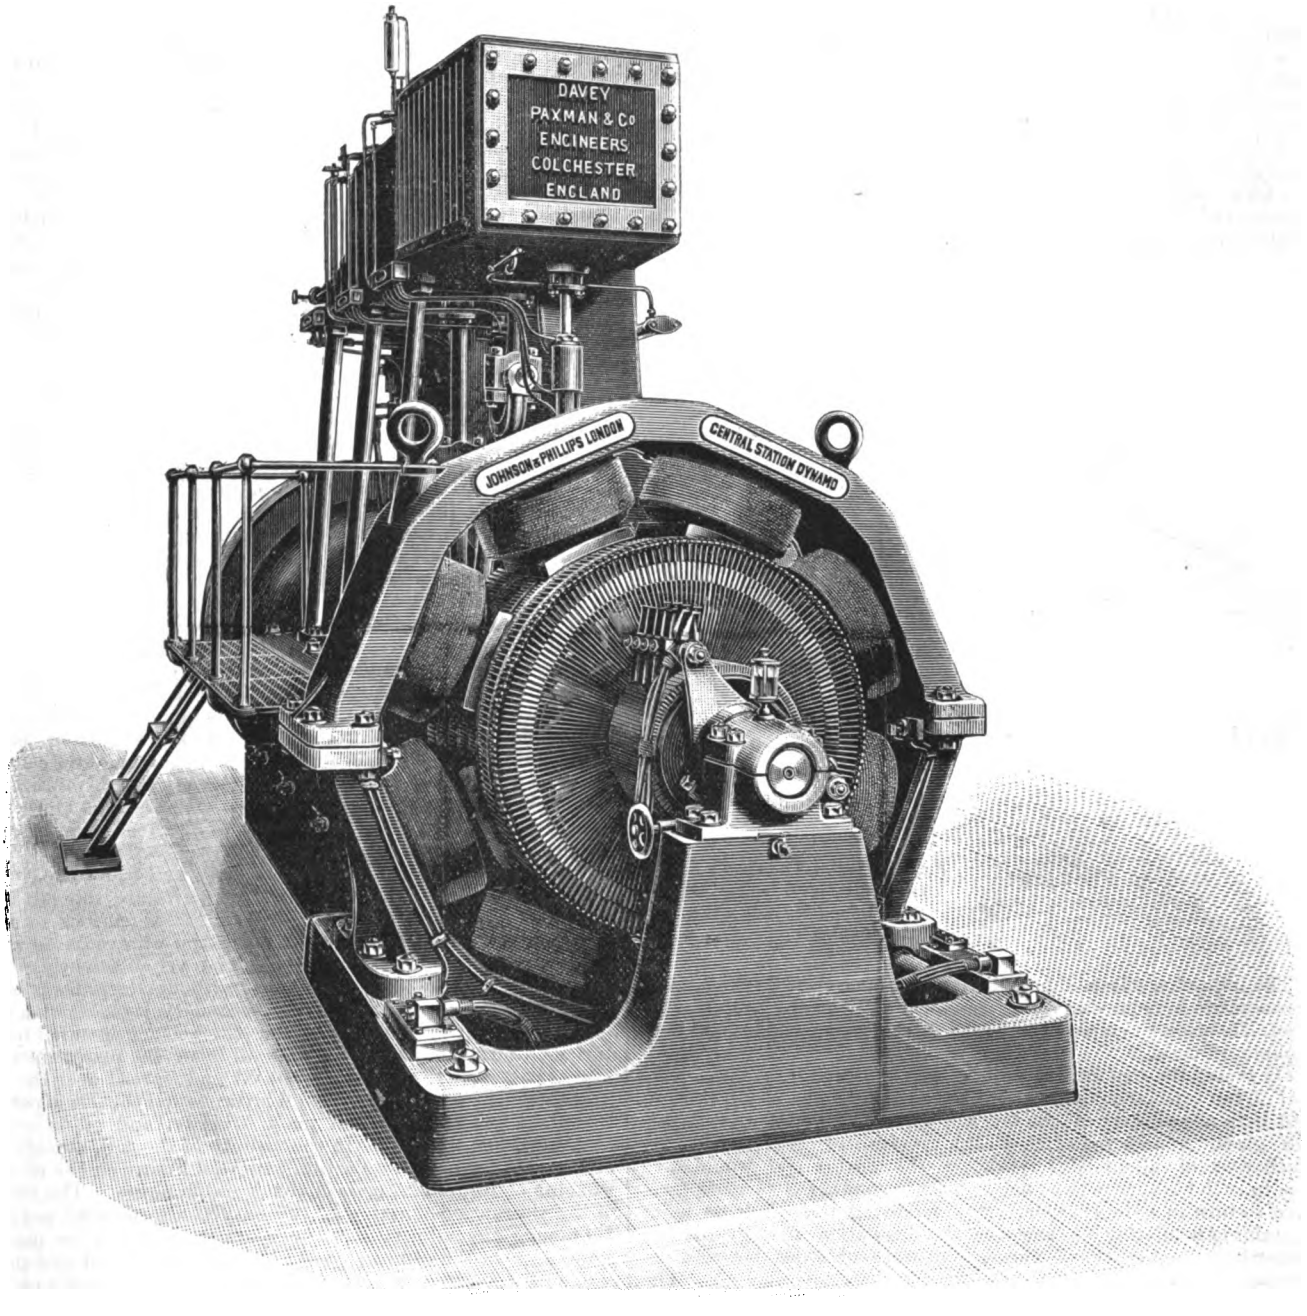
The accompanying illustration represents the large steam dynamo, jointly exhibited at the Crystal Palace by Messrs. Johnson and Phillips and Messrs. Davey, Paxman and Co. The machine, which was designed by Mr. Kapp. has eight field poles, projecting radially inwards from a massive cast-iron yoke ring. The magnet cores, which are cylindrical, and 14½in. diameter, and the rectangular pole pieces, are also of cast iron. The armature core is 48in. diameter by 18in. long, and is built up of segmental plates, threaded on steel bolts and secured between strong cast-iron end cheeks. The power is transmitted to the armature conductors by 64 metal driving horns, insulated with fibre and mica; the force transmitted by each driving horn being about 50lb. There are 362 bars on the armature, and the ends are connected by segmental plates and insulated from each other and mounted in cast-iron carriages, which latter are screwed to the end cheeks above mentioned. This method of end connections has the advantage of leaving the ends of the armature perfectly open, which admits of excellent ventilation inside and of avoiding the crossing of conductors over the ends, which, in the old-fashioned way

Digitized by Google

of drum winding, is so frequently a source of trouble. The difference between adjacent plates is only 10 volts.

The commutator contains 181 sections, and is 20in. in diameter and 12in. long. The current is taken off by two sets of brushes, placed 135deg. apart, four brushes in each set. The machine is designed for an output of 550 amperes, at a voltage which can be varied at will, from 200 to 260 volts, at 130 revolutions per minute; but as at the Palace a voltage of 205 volts only is required, the engine governor has been adjusted for a speed of 115 revolutions per minute. The brushes are adjustable by worm gearing. The current from the machine is used for lighting the Picture Gallery by incandescent lamps (which have been fitted up by the Gülcher Company), also for some Gülcher arc lamps, and for a number of Brockie-Pell lamps, as well as for driving all the machinery on Messrs. Johnson and Phillips' stand. For the latter purpose the current is passed through a pair of small balancing dynamos, which split up the current into 70 and 130 volts, so as to make the current suitable for charging cells.

The engine is triple-expansion, having cylinders 12in., 18¾in., and 30in. diameter respectively, with a stroke of 18in. It is built for an I.H.P. of 350 at 140 revolutions, or is 320 I.H.P. at 130 revolutions, and 160lb. steam pressure. The floor space, including platform, is 10ft. 6in. by 6ft. 9in., and from the floor line to top of cylinder covers is 11ft., the extreme height to top of sight-feed lubricators being 3ft. 2in. more; the platform is 2ft. 8in. above level floor. The steam is supplied from Paxman's water-tube boiler at 130lb. pressure; and for the purpose of starting the engine in any position steam can be admitted direct into the intermediate steam chest. The crank-shaft is of mild steel, with slotted cranks 120 degrees apart, and runs in four long bearings.



143 Kilowatt Multipolar Kapp Dynamo and Davey Paxman Triple-Expansion Engine.

The governor is of Paxman's improved design. The governor pulls over a link, bringing the short-throw eccentric into action with expansion valve spindle, and cuts off steam earlier, keeping the speed constant. The three main concentric rods are of best forged iron, finished bright, with adjustable bushes. The automatic gear is of steel, with forked joints fitted with steel pins. The piston-rods, crossheads, slippers, and valve spindles are of forged steel, the latter being swelled to work in guides. The connecting rods are of best forged iron. The fly-wheel is 6ft. diameter.

INDUCTION BY HIGH-POTENTIAL DISCHARGES.*

BY ELIHU THOMSON.

In working to devise a means for the protection of electrical apparatus from the effects of induced discharges of lightning, it occurred to the writer to employ the inductive effects of the discharges, or, as it were, to interpose a barrier between the discharges and the apparatus to be protected. This gave rise to a lightning-discharge protector or lightning arrester, the principle of which is shown in Fig. 1. Let L be a line leading from a dynamo D, and subject to induction from lightning discharges, or subject to lightning discharges themselves, as in a railway trolley line. To avoid them he places between the dynamo and the line a double coil, each coil being made of a few turns of coarse wire highly insulated from each other. One of the coils may be wound upon the outside of a glass cylinder and the other coil may be wound in the interior. Both are connected to line at one end, as shown, and one or both are connected to earth through the discharge plates of a lightning arrester A, provided with an arc-rupturing device, such as a magnet to blow out the arc in case the potential of the dynamo is high enough to maintain such an arc. The coil in the dynamo circuit has been found to need a few more turns than that in the earth circuit, and the direction of winding in the two coils is such that they are opposed in their inductions.

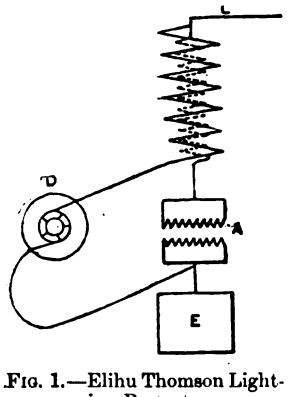

FIG. 1.—Elihu Thomson Lightning Protector.

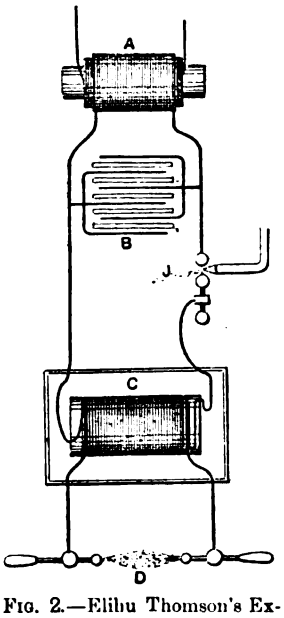

FIG. 2.—Elihu Thomson's Experiments on Electric Discharges. — Diagram of Arrangements.

The induction effects obtained with apparatus used in the experiments made in connection with this form of lightning protector led Prof. Thomson to employ condenser discharges in connection with Ruhmkorff coils.

On trying the experiment with a coarse heavily insulated wire coil of ten turns, enclosed in a glass tube, without any iron core, and with a secondary of one layer of fine silk-covered wire outside the glass, it was found that the passage of the Leyden jar discharges of about ¼in. spark in the coarse coil would give rise to such high inductive effects in the secondary as to spark from turn to turn in a single layer. By immersing the whole in a jar containing insulating oil, however, the insulation of the turns was better kept, and sparks of 2in. or 3in. were obtained between the terminals of the secondary at every discharge of the jar. The glass tube used was about 2in. in diameter and about 5in. long. There were about 120 turns in the secondary layer. The induction must have been at least as high as from 100 to 150 volts to the inch of wire. It was soon found that the glass tubes ¼in. thick were frequently punctured under the oil, and that the spark of the jar could not be unduly lengthened without producing discharges under the oil, or between turns of the secondary.

Arrangements were now made to obtain frequent condenser discharges at high potential, and to carry on the experiments on a much larger scale.

In Fig. 2 is a view of the apparatus used. A is a large induction coil or transformer, capable of using in its primary ordinary alternating lighting currents of 50 to 100 volts, and transforming up to 10,000 to 12,000 volts alternating. So used it will spark over one-half to one inch between its terminals and give the uprising thin arc now well known. A blast of air blown on such an arc changes it into a beautiful pale purple flame. A condenser B, the capacity of which can be changed, is connected to receive the current from the secondary of A. The spark or arc with moderate condensing capacity is not much changed unless a blast of air be blown upon it. In this latter case it displays a most beautiful electrical phenomenon. It becomes a mass of flame filled with fine and thick threads representing the condenser discharges, a gorgeous network of electric fire changing with any change of the pressure or direction of the air blast. Sometimes, as on breaking the primary circuit, the oscillations of charge and discharge are seen as minute parallel lines or sparks on the borders of the flame joining the terminals. With greater condensing surface the discharge between terminals becomes more thick and white even without the blast, and when a forcible air jet is turned on it roars very loudly. At C is a second and peculiar transformer, the primary of which is an open helix of but a few turns as 15 or 20 convolutions of heavily insulated line wire about four or five inches in diameter. This is surrounded by a thick glass cylinder, upon which has been wound say 150 turns of fine silk-covered wire in one layer, with a silk thread between the turns so as to cause the turns to be well insulated laterally. This simple induction coil is now immersed in a jar of heavy oil, and the terminals on leaving the oil kept as far apart as possible and surrounded by glass tubes. The terminals of the coarse and short primary are connected in circuit with the discharge balls upon which the jet of air plays at J. The finer secondary terminals are connected to discharge terminals as at D for obtaining the spark. On passing the alternating currents in the primary of A, and adjusting the spark gap and jet at J, as well as the distance between the discharge terminals at D, it is easy to obtain sparks of 7in. to 8in. in a perfect torrent at D, while sparks of ¼in. are passing at J.

The discharges obtained at D represent, it would appear, at least 150,000 volts in potential, or about a thousand volts to each turn of the secondary. The potential may be higher, for we have no data of spark length at such high pressures. It should be mentioned that the limit of spark was apparently that of the insulation of the secondary turns, for on attempting to increase it by separating the terminals at D to over 8in. the sparks jumped in the jar of oil, and could be seen passing under the oil from the secondary to the primary wires. Were it not for the required insulation between the turns of the fine wire secondary of C, they could be wound in one layer so as not to cover more than two or three inches of the glass cylinder, and could be made to give out sparks of a foot or more in length. The volts per inch of wire obtained in these experiments are extraordinary, and it is quite certain that the limit will depend on the insulation. We are now possessed of the means of obtaining artificial lightning in a steady stream, and can experiment at will with extremely high voltages. The advantages of oil insulation are emphasised by these experiments, and although sparks frequently passed under the oil the insulation is renewed at once.

It is necessary that the coil C be sunk well below the surface of the oil, as otherwise the discharges will perforate the oil layer at each end and pass over the surface. It is curious to note the agitation of the oil over the coil when the apparatus is in action and the coil is not deeply immersed and yet sufficiently so to prevent discharge. A curious discharge without electrodes is obtained by providing each terminal of the secondary layer C with a metal plate, which the oil just covers, the plates being parallel to the oil surface. Great agitation of the oil over the plates ensues, and sparks pass over the surface of the oil and spread over the surface just above the plates. If the oil layer be too thin it is perforated by discharges passing from plate to plate, and oil is scattered. Geissler tubes are lighted in the vicinity of the coil, outside the jar or near the terminals, an action long well known in the case in the working of Ruhmkorff coils of considerable power. The frequency of the alternations used was 125 or 250 alternations per second. By raising the alternations the spark torrent will be more continuous. On the completion of still more powerful and perfectly insulated apparatus the effects will doubtless be greatly enhanced.

The experiments demonstrate that lightning discharges, aside from electrostatic effect, may be the source of most vigorous electrodynamic inductions, and that high potential discharges may result.

* Abstract from *The Electrical World* of New York.

Institution of Electrical Engineers.—At a students' meeting held at the Library of the Institution on Friday, 26th ult., Mr. W. B. Esson presiding, Mr. Wharton read a Paper on "House-wiring." At the next meeting, on the 11th inst., two short Papers will be read—on "Electrometers," by Mr. M'Dowall, and on "Electric Welding," by Messrs. M. S. Poore and C. V. Drysdale.

Digitized by Google

ON THE SPECIFICATION OF INSULATED CONDUCTORS FOR ELECTRIC LIGHTING AND OTHER PURPOSES.

The following is the authorised abstract of the discussion on the above Paper, read before the Institution of Electrical Engineers by Mr. W. H. Preece, on December 10, 1891 (see *The Electrician*, December 11, page 146).

THURSDAY, FEBRUARY 11TH.

Mr. PREECE said that some time having elapsed since reading his Paper he wished to add some further remarks to it. In the matter of india-rubber insulation durability was a quality which was quite as important as high insulation resistance. Though the initial insulation resistance might be very high, it by no means necessarily remained so; in fact, he always rather mistrusted rubber which had an abnormally high insulation; and in the case of gutta-percha it was well known that high resistance was generally accompanied by a want of durability. At the General Post Office rubber was tested by exposing it to a dry heat, 270° F., for one hour, and then to a moist heat, 320 F., for three hours. A rubber which stood this test could, he thought, be depended on to last some 15 years in a cable if not heated by an excess current. He had arranged that at the next meeting there should be exhibited some samples of rubber thus tested. Referring to oil insulation, he wished to call attention to a Paper read by Prof. Hughes in 1854, before the Society of Arts "On a Semi-Fluid Insulator," in which he proposed to cover a cable with gutta-percha or other substance, draw it into a pipe, and fill the latter up with oil or other semi fluid, pointing out that if the insulation was broken down it was immediately re-established. Referring to Mr. Siemens' Paper, Mr. Preece remarked that these tests were all on new cables, and must be taken as giving the limiting pressures they could bear under the best conditions. In practice it was necessary to allow for fissures in the insulation, the surfaces of the wire being dirty and the edges of the cracks possibly damp. He thought, therefore, that 500 volts per millimetre of insulation was probably as much as could be safely permitted in practice. Referring to the closeness between the results of Mr. Siemens and the previous ones of Mr. de la Rue, he said it was the first time he had ever found two experimenters who could agree about a sparking distance.

It was mentioned that at the next meeting Major Cardew would open the discussion, and show an electrometer method of measuring insulation resistances up to 250 000 ohms.

THURSDAY, FEBRUARY 18TH.

Major CARDEW showed an electrometer method of testing high insulation resistances. (See *The Electrician*, February 26, p. 430.)

Mr. ROBERTS, of the General Post Office, showed the apparatus used by that Department for testing rubber for durability. He mentioned that analysis had shown some samples tested to be adulterated with French chalk, pitch, resin, asphalt, silica, and old rubber. The samples were tested dry in a small copper oven heated by a gas jet to 220 F., and, wet, in an ordinary dentist's vulcaniser, also heated by a gas jet. This was half filled with water, the samples were placed in it, the top fastened down, and a safety-valve on the top, set to blow off a 90lb. pressure, which corresponds to a temperature of 320 F. The apparatus cost from £3 to £4. Samples which had passed these tests were shown, and also some which had failed.

Mr. GRAY thought Mr. Preece was mistaken in saying that engineers did not pay attention to the lasting properties of insulation in cables, as he thought they were fully alive to its importance. The figures given in the Silvertown lists were, he said, merely the minimum values. As the size of cables increased the thickness of insulation also increased, but not proportionately, and consequently the insulation resistance per mile was less in the larger sizes. He wished that some standard time of electrification could be agreed on in testing. One minute was most usually adopted, but some makers allowed five minutes. He believed in using high-battery power for tests; it broke down faults, but did not injure good cable. He considered the sparking distance in air had no bearing on the thickness of insulation required. Durability he considered to be in no way dependent on initial insulation resistance. He had a cable tested every fortnight for five years, which began with 9 (Preece) units of insulation and remained at the same figure still; another kept perfectly steady for the same time at 6 units; while a third, which began at 4, had fallen to ·4. Some high-insulation cable would, moreover, spark through at an E.M.F. which would not break down other cables of lower resistance. He did not consider that the heat tests applied by the General Post Office were by any means infallible. He had with him some samples of rubber which he had received from America. They were made from old ground-up galoshes, but they would pass the General Post Office heat tests perfectly.

Prof. FORBES said he was startled to hear Mr. Gray's last remark, but still thought that the test was a step in the right direction; even if all that passed it was not necessarily good rubber, it at any rate detected a good deal that was bad. He objected to Mr. Preece's statement that specific insulation resistance was not mentioned in specifications; a resistance of so many megohms per mile, when the diameter of core and thickness of covering was given, defined the specific resistance perfectly; but he agreed that Mr. Preece's method of expressing it was much more convenient. He quite agreed that high-insulation resistance was no criterion of durability. He did not believe in basing the thickness of insulation on the sparking distance in air, as this only came in in the case of a crack. Bad cable would crack, however thick the insulation, and a cracked cable was always dangerous. The proper thickness depended on mechanical considerations only. He believed the safest thing was to go to a manufacturer with a good reputation, and to trust to his not risking losing it by turning out bad work.

Mr. CROMPTON thought that Mr. Preece's specification would not mend matters much, and would prefer to trust to a maker's reputation. He considered the Board of Trade requirements quite insupportable. He had cable which passed all their requirements except thickness of insulation, which was better covered, and he considered much safer and more durable, than what they would pass. The latter, with its thicker insulation, was far more liable to kink and crack. To fulfil the Board of Trade requirements, makers would have to supply inferior insulating material on account of excessive cost. Engineers ought to combine to make a firm stand against the thickness required by the Board of Trade. What was wanted was a thin covering, of the very best material and make. Such a cable would never crack.

Mr. RAWORTH said it was rather a shock to hear that high insulation resistance was no proof of goodness. Referring to the numbering of cables, he said that at the Brush Company the wires were called according to the section in thousandths of a square inch, *e.g.*, 7/16 was No. 23. The number gave, therefore, the current the cable would carry at 1,000 amperes per square inch, and the number × 40 gave yards to the ohm. For alternating work he found a useful formula for leads was 2,000 volts on 2,000 yards of main; allowing 2 per cent. loss in mains meant 2lb. of copper for every two lamps.

Mr. SIEMENS referred to the influence of E.M.F. used in testing insulation resistance, and gave the following results:—

	R. with 100 cells.	R. with 1,200 cells.
Gutta-percha core	3.468 Ω	3.021 Ω
India-rubber core	8.054 „	6,245 „
Lead-covered cable	2.600 „	1.708 „
Ditto	2.600 „	2.200 „

High E.M.F.'s did not necessarily affect the insulation resistance of a cable, as he had some which was in daily use during the Frankfort Exhibition at 30,000 volts, and which came back with the resistance unaltered.

THURSDAY, FEBRUARY 25TH.

Mr. STEWART RUSSELL denied any connection between insulation resistance and durability, quoting cables of 14 and 0·6 Preece units respectively, which had lasted perfectly constant for 4½ years, while one of 3·8 came down to ·35 in the same time. Sparking distance in air was also quite irrelevant; for a good cable the air spark thickness was far greater than necessary, and for a cracked cable very much too small. Mr. Preece quoted the Board of Trade rules, but it was well known that these quite ignored quality, and their natural result was the use of thick bad quality insulation which would not last. The speaker then quoted some tests, showing that the E.M.F. to break a cable down did not vary directly with the specific resistance; also some on the effect of time in breaking down tests. From these he showed that a high pressure does not permanently alter the insulation of a cable unless there is an incipient fault. As a practical test he would measure the insulation resistance of a cable, then subject it for some time to three times its working pressure, and pass it if the insulation remained the same afterwards.

Mr. SWINBURNE said sparking distance in air had nothing to do with anything. In large wires the insulation was subject to approximately an even strain throughout its thickness; but in the case of a small wire the strain might be very uneven, being much greater, close to the wire, than at the outside. If anything, therefore, a small wire should have a thicker covering than a large one. When testing a long cable at high volts, the "condenser current" became large, necessitating a large dynamo; but this could be overcome by putting a big choking coil in series with the cable.

Mr. ESSON would allow 2 per cent. drop instead of 1 per cent. in the leads, as in Mr. Preece's specification, as only one-half the lamps would be on at once. He would also add a clause that the current should never exceed 1,000 amperes per square inch.

Mr. MAVOR instanced the case of a large order for cable which had been made with the utmost exactness to the specification based on experiments of the engineer who ordered it, and which failed completely. He objected to men without practical experience in cable manufacture specifying the thickness, &c., of insulation.

SOME EXPERIMENTAL INVESTIGATIONS OF ALTERNATE CURRENTS.*

BY ALEXANDER SIEMENS, MEMBER.

(*Continued from page 434.*)

In order to determine the variation of the efficiency of the transformers under investigation, it is necessary to treat separately the losses in the iron and in the copper. The former can be found by the aid of the curves on Diagram I., in combination with the curve giving the weight of iron necessary at the various inductions.

An example will best illustrate how this loss is ascertained in a case where the total mass of the iron is worked at the same induction, produced by a current of a frequency equal to 100 ∿ per second, the iron mass being composed of 1mm. wires. The loss in the normal transformer working with an induction B = 5,000, and

* Paper read Thursday, 11th February, 1892, before the Institution of Electrical Engineers.

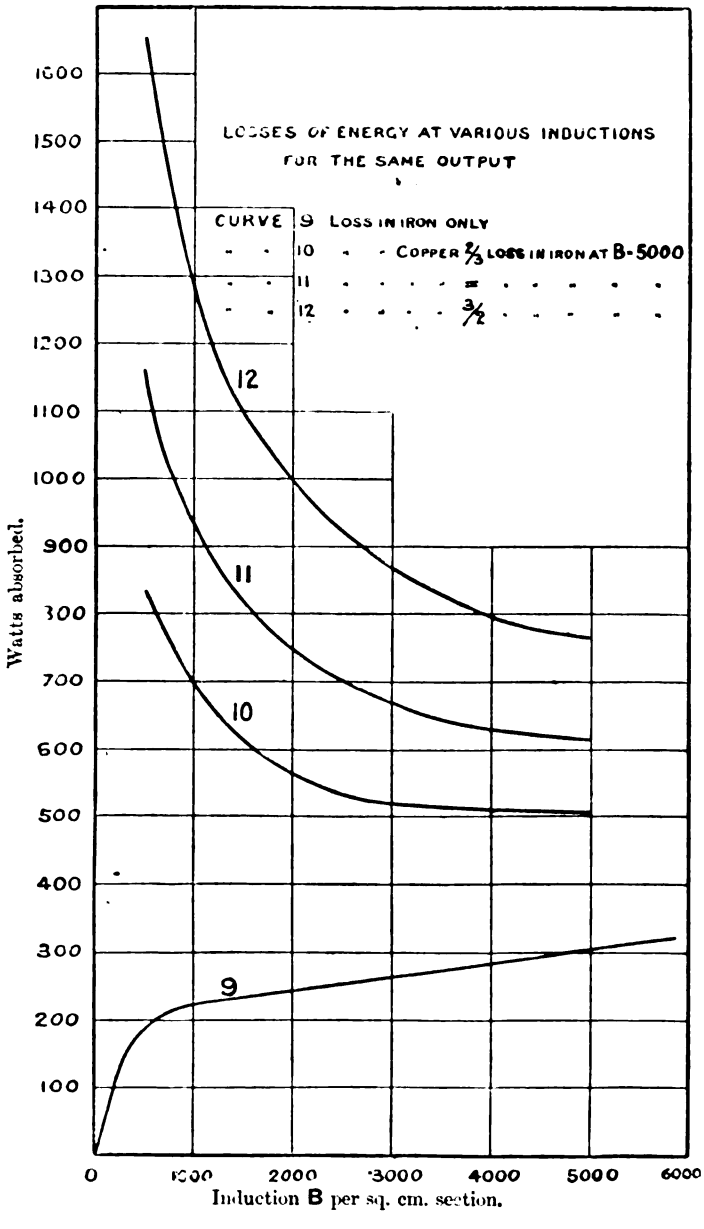
with a weight of iron=1 cwt., is 309·6 watts, according to Diagram I. For another transformer working with an induction B=2,500, the weight of iron, as shown by the curve (7), has to be increased to 2 cwt. ; at the same time the loss per cwt. is reduced to 126·8 watts, or the total loss is reduced to 253·6 watts.

In a similar manner the losses for the different inductions have been calculated, and the results are embodied in a curve (Diagram IV., No. 9) which indicates that the loss of energy in the cores of transformers increases with the strength of induction, at first rapidly, but after the induction has reached a value of B=1,000 the increase is very slow. As far as the loss of energy in the iron goes, it is therefore of not much consequence what induction between 1,000 and 5,000 lines per square cm. is used. The influence of the strength of induction on the loss of energy in the copper can be shown in the simplest manner by comparing this loss in the normal transformers designed for 5,000 lines with the loss in the other transformers of the series.

DIAGRAM IV.



There are evidently three possible cases for the normal transformer : the loss in the copper may be equal to the loss in the iron, or it may be greater, or it may be less. For each of these cases a curve can be plotted showing the sum of the losses in the iron and in the copper at the corresponding induction. If we take, for instance, the case that the losses in copper and in iron are equal, the total loss in the transformer having an induction B=5,000, is 2×309·6 watts. For the transformer having an induction B=2,500 the loss in the iron is given in our curve 9, and the loss in the copper is in proportion to its weight, which varies in accordance with curve 8, or, in this particular case, the loss is = $\sqrt{2}\times 309{\cdot}6$ watts. In this way curve 11, Diagram IV., has been plotted for the case of the losses being equal, curve 10 represents the case where the loss in the copper is equal to two-thirds of the loss in the iron, and curve 12 where the loss in the copper is 50 per cent. greater than the loss in the iron. Taking these curves to represent generally the variation of the total loss at the various inductions, it appears that, when keeping the loss in copper small in comparison with the loss in iron, it is quite possible to obtain about the same efficiency with any induction between 2,000 and 5,000 lines per square cm., but if a lower induction is used the efficiency, even on full load, decreases very rapidly.

From the consideration of efficiency it is, therefore, desirable to work the transformer with a high induction, and it is only the question of the heating of the apparatus which imposes restrictions on the use of high inductions, to avoid the destruction of the insulating material. In other words, the problem was to find the maximum internal temperature of a body of known dimensions when the rate at which its mass is heated has been determined.

In order to obtain some data towards the solution of this problem, a solenoid was constructed by winding 18lb. of insulated iron wire, 2·4mm. in diameter, on a brass tube 300mm. long, 8mm. internal diameter, and provided with flanges at the ends each 100mm. diameter. The internal temperature was measured by means of a thermometer just fitting the brass tube, and due care was taken to keep the temperature of the surrounding air constant during the experiments. A constant direct current was sent through the coil, and a reading of the thermometer was taken after it had ceased rising. The rate at which energy was supplied to the coil was determined by the product of the square of the current into the resistance of the coil, measured when the equilibrium of temperature had been attained. By varying the current the internal temperature could be varied, and the results were plotted in curve 13, the abscissæ of which represent the cooling surface in square centimetres per watt dissipated, and the ordinates indicate the excess of the internal temperature of the coil over the temperature of the surrounding air in degrees centigrade, after the equilibrium between the supply and the dissipation of energy had been established in each case.

This curve is a rectangular hyperbola of the equation, $x\,y=1{,}500$, and it shows that if the temperature of such a coil is to be kept at 100°C. the cooling surface should be 15 square cm. for each watt converted into heat in the coil. It is self-evident that this curve (Diagram V., No. 13) relates only to the coil by the aid of which it was constructed, and that it can only serve as a guide under strictly similar circumstances. By way of comparison a set of experiments was made on the same lines with a cable transformer, hung up in air, 6 metres long and 9·5cm. in diameter, the internal temperature of which was determined by means of a test wire, as described above. This curve (Diagram V., No. 14) shows that for an internal temperature of 100°C. a cooling surface of about 23 square cm. has to be provided per watt of energy converted into heat in the transformer.

Before it is possible to draw general conclusions as to the connection between the internal temperature of transformers and their cooling surface, it is obviously necessary to make a good many more experiments in the direction indicated by the two curves just described.

Last year Dr. Fleming read a Paper before this Institution, "On some Effects of Alternating-Current Flow in Circuits having Capacity and Self-Induction" (*Journal of the Institution of Electrical Engineers*, Vol. XX., No. 94, p. 374); it is, therefore, not necessary to repeat here the results of some experiments which were brought to the notice of the Institution at that time.

A very important factor in the construction of alternate-current apparatus is the striking distance of these currents in various materials, as this determines, in the case of high-voltage currents, the thickness of the insulating material with which the conductors have to be surrounded, the ohmic resistance being no guide.

The first set of these experiments referred to the striking distance in air. In all the experiments made the frequency of the alternate current was 100 ∿ per second, except where another frequency is specially mentioned, and the voltage was produced by means of an alternate-current machine and a transformer, and it was measured by one of Sir William Thomson's static voltmeters. The electrodes were re-polished each time a spark had passed between them ; one of them was fixed horizontally during the experiments, while the other could be advanced towards it from above by means of a micrometer screw which allowed of reading to a hundredth of a millimetre.

The experiments were made in the following manner :—After connecting the electrodes of the spark micrometer to the terminals of the transformer, a certain voltage was put on and accurately measured ; the distance between the electrodes was then slowly diminished until sparking occurred. Each experiment was repeated at least three times. Various electrodes were experimented with, the first pair being two plane parallel surfaces. In this case the fixed horizontal electrode consisted of a polished brass disc about 100mm. in diameter, while the movable electrode was also formed by a brass disc, but only 37mm. in diameter. To prevent the

action of sharp edges, the edges of the discs were rounded off. The temperature of the surrounding air during these experiments was 14·75°C.

The results obtained are as follow :—

Difference of potential.	Striking distance.	Difference of potential.	Striking distance.
volts.	mm.	volts.	mm.
2,000	0·67	10,000	4·80
4,000	1·59	12,000	6·46
6,000	2·53	15,000	10·23
8,000	3·60		

The last reading, giving the striking distance for 15,000 volts, cannot be correct, as the sparks started from the upper edge of the smaller disc, and not from the nearest points between the two discs, the smaller disc being placed above the fixed one.

Curve 15 (Diagram VI.) is the graphic representation of the above table.

For the next series the arrangements were the same as before, with the exception that the smaller movable disc was replaced by a half-sphere of 10mm. diameter. The temperature of the air during these experiments was from 16° to 17° C., and its humidity 80 per cent.

Difference of potential.	Striking distance.	Difference of potential.	Striking distance.
volts.	mm.	volts.	mm.
2,000	0·45	10,000	4·37
4,000	1·40	12,000	5·65
6,000	2·30	14,000	7·32
8,000	3·25	15,000	9·02

These results are plotted in curve 16 (Diagram VI.).

After this the movable electrode of the spark micrometer was replaced by a steel point of an angle of 60deg., its section being an equilateral triangle of 5 mm. sides. This point was also re-polished after each spark ; the spark, however, did not always start from the point. During these experiments the temperature of the air was 12° C., and its humidity about 50 per cent.

Difference of potential.	Striking distance.	Difference of potential.	Striking distance.
volts.	mm.	volts.	mm.
2,000	0·40	10,000	5·78
4,000	1·26	12,000	7·60
6,000	2·66	14,000	9·37
8,000	4·08	15,000	10·70

Curve 17 (Diagram VI.) embodies this tab'e.

After this the influence of an alteration in the frequency was tried by lowering this to 80 ∿ per second, and repeating some of the first experiments with disc electrodes. The striking distances for 4,000 volts and for 6,000 volts under these circumstances were found to be 1·47 mm. and 2·30 mm., or only slightly different from those produced by a frequency of 100 ∿ per second. From theoretical considerations it might have been expected that the distances would vary directly as the frequencies.

In order to investigate the influence of capacity, one or more coils of gutta-percha-covered wire were connected to the circuit of the transformer in parallel with the spark micrometer. The first experiments were made with a frequency of 100 ∿ per second, the two disc electrodes, and a capacity of 0·113 microfarad. The temperature of the air was 16·5°C., and its humidity 79 per cent.

Difference of potential.	Sparking distance.	
	With capacity.	Without capacity.
volts.	mm.	mm.
4,000	1·53	1·59
6,000	2·21	2·53
10,000	4·17	4·50

A further experiment under similar conditions, but with a capacity of 0·28 microfarad in circuit, showed that the sparking distance at 10,000 volts was further reduced to 3·94mm.

These tests were repeated with other electrodes, viz., the spherical surface and the disc.

At a difference of potential of 10,000 volts the sparking distance turned out to be—

1. With 0·14 microfarad capacity in circuit ..... 4·08mm.
2. Without any ,, ,, ... 4·50 ,,
3. With 0·14 microfarad ,, ,, ... 4·06 ,,

After that the steel point and the disc were used as electrodes, a capacity of 0·14 microfarad being connected to the circuit, and the results were :—

Difference of potential.	Sparking distance.	
	Without capacity.	With capacity.
volts.	mm.	mm.
4,000	1·26	1·14
10,000	5·78	4·83

All these experiments point to the fact that the sparking distances in air are diminished to a slight extent when capacity comes into play.

With a view of ascertaining how the voltage is propagated along a circuit, the position of the micrometer relatively to the cable was varied.

The experiments detailed above were made with the spark micrometer connected to the beginning of the cable ; they were afterwards repeated after inserting the spark micrometer in the middle of the cable, and again after it had been connected to the end of the cable. In all three positions the same striking distance was observed under similar circumstances, which tends to prove that the voltage is propagated uniformly over the whole length of conductor, even if there is capacity in some parts of the circuit.

As stated above, the voltage experimented with was measured by means of Sir William Thomson's static voltmeters ; but it is undoubtedly the highest ordinate of the wave which causes the spark. This "real" voltage can be found, if sine waves are assumed, by multiplying the measured volts by $\sqrt{2}$, and these new figures should be applicable to constant continuous currents.

In this way the results of curve 15 were corrected, and compared with some results published by Warren de la Rue in *Nature* on September 12, 1878. Assuming that the E.M.F. of his cells was equal to 1 03 volts, and reducing his results to volts and millimetres, they compare as follows :—

Difference of potential.	Striking distance.	
	Warren de la Rue.	Siemens.
volts.	mm.	mm.
2,000	0·45	0·25
4,000	0·95	0·80
6,000	1·55	1·45
8,000	2·15	2·15
10,000	2·85	2 85

On referring to the other curves published at the same time, it will be seen that Warren de la Rue found the sparking distances between two plane surfaces and between two spherical surfaces not to differ very much from each other. It may, therefore, be allowable to compare the mean values of these two curves of his with curve 16 for the sparking distance between a hemisphere and a plain surface after the values of the volts have been multiplied with $\sqrt{2}$.

Difference of potential.	Striking distance.	
	Warren de la Rue.	Siemens.
volts.	mm.	mm.
2,000	0·36	0·25
4,000	0·87	0·80
6,000	1·50	1·45
8,000	2·10	2·16
10,000	2·75	2·85

Both these tables show that the results are practically identical, and, consequently, it may be concluded that the secondary current of the transformer used for the experiments is really a sine function.

(To be continued.)

LEGAL INTELLIGENCE.

Lane Fox v. Kensington and Knightsbridge Electric Lighting Company (Limited).

THURSDAY, FEBRUARY 25th.

Cross-examination of Prof. PERRY continued by Sir HORACE DAVEY: Do you remember telling us on Tuesday that you yourself used the Lane Fox system for the dining-room of the Grand Hotel, at Charing Cross?—Do you mean by that including the accumulators?

I will read you what you said:—"I myself used the Lane Fox system for first lighting up the dining-room of the Grand Hotel, at Charing-cross." Do you remember that?—Yes, and I meant to include accumulators.

And what you meant was the combination of accumulators with the Lane Fox system?—In the patent Lane Fox speaks of combining accumulators with his system.

At all events, I think we understood what you meant, and that my lord understood also. I want to know if the attempt was successful.—It was successful at the beginning.

For how long?—For a few days.

And then broke down?—No.

It was unsuccessful at the end?—We naturally added cells to prevent the lamps going a little too high and a little too low.

Did you not find it necessary at the Grand Hotel, Charing-cross, for the successful working of that system to introduce your arrangement, by means of switches or otherwise, by which you could throw certain cells in the accumulators out of use, and, when necessary, introduce other cells into use? Can you answer that, yes or no?—With our set of cells, yes. My set of cells was too small. I could have done it in two ways.

Cannot you answer my question? I will put it again, and I shall be much obliged, subject to my lord's direction, if you will be kind enough to give me a direct answer, yes or no. Did you find it necessary to introduce arrangements by which you might from time to time introduce fresh cells into operation or exclude cells from operation?—Yes.

But it was a small installation.—It was the largest then in use, I think.

But as compared with the installations for the present day it was a small installation.—Yes.

Mr. JUSTICE A. L. SMITH: Did you give the date for this?—I think it was at the end of 1882 or the beginning of 1883.

Sir HORACE DAVEY: Did you not try various devices for the purpose of bringing cells into action and throwing cells out, and did you not make serious experiments?—Yes, and took out patents for switches. Our main difficulty was the badness of our cells.

Now can you tell me of any single successful installation which has been made of the Lane Fox system described in the patent, I of course include accumulators—including the combination that is claimed—any successful installation of the combination claimed by Lane Fox in his patent, without introducing switches or other arrangements for regulating the number and altering and varying the number of cells which from time to time should be in operation?—Do you mean in use at the present day?

At any time since 1878—I consider my installation—— Oh, there is the one described which I spoke of as being at Glasgow University, and that was certainly successful.

Are you going to give any evidence on that—I mean, you know nothing more than the description in *The Electrician*, as I understand?—No.

Now you have told us that you have experimentally—I use your own language—"If your cells are to work at 100 volts you can charge those cells at 101 volts, because I have tested it experimentally." I should like a little further information about that, what was the nature of your experiment, you have tested it experimentally? Understand, the point is this: I am instructed by a gentleman who is conversant with the subject that, in order to charge a secondary battery fully, the charging current must be raised gradually from 100 to 125 volts; those are my instructions, and I will give evidence on that point, therefore I want to ask what are the experiments?—I have made several.

Mr. JUSTICE A. L. SMITH: You say you can charge it with 101?—Yes, my lord, 101, with a very small increase.

Sir HORACE DAVEY: Do you mean charge it completely?—I mean that your charging current—that when you current is charging—it need only be very little above the normal voltage, and when you discharge from the cells your leads get only a little less than the normal voltage.

Prof. PERRY then described experiments made with small currents and small cells, in one case on a single cell, and in another on 48 cells; the experiments lasted six or seven hours. He said that using a large battery comes to the same thing as using a smaller current. Switches for altering the number of cells were not required when large enough batteries were used.

Will you say as an electrician that earth alone—the soil alone, having regard to the large quantity of current which is required for the purpose of electric lighting—would be a sufficient return conductor?—Do you mean better than copper?

I ask you whether it would do at all?—It will work, and work quite successfully. If the Board of Trade would allow me, and I was distributing anything over two or three miles, I would use the earth as a conductor if the Board of Trade and insurance companies would let me. It is merely a question of the degree of cost.

[Witness produced "Munro and Jamieson's Pocket Book," in which the return circuit on board ship is called "earth."]

Prof. PERRY was re-examined by Mr. MOULTON: He described the process of charging and discharging a battery. He said that if an earth plate of platinum were used it might be very thin. In further cross-examination he said that if the range of variation in the Kensington batteries is 10 per cent., a battery twice as costly would have a range of about 5 per cent. He thought that plates five times the size would be sufficient to allow switches to be dispensed with. It was put to him by Sir HORACE DAVEY that the plates at Kensington are about a foot by fifteen inches. He was asked whether he had ever seen a plate five times this size? He replied that five times as many of the same size would do.

WITNESS was briefly re-examined by the ATTORNEY-GENERAL.

Mr. ST. GEORGE LANE FOX, examined by the ATTORNEY GENERAL, said that he carried on no profession, but had for many years studied electricity. He had managed practically manufactories and works, although he had not been solely dependent upon that for his living. He had taken out earlier patents before that of 1878, and had worked at distribution of electricity for other purposes, such as the lighting of a number of gas lamps. He was prepared to give any explanation or to answer Sir Horace Davey's questions as to why no proceedings were taken before. An action was brought before this one by the Brush Company, who owned his patents. It was afterwards compromised. The Brush Company brought an action against the Edison-Swan Company. It was begun in 1886.

Mr. JUSTICE A. L. SMITH: That was compromised?—Compromised. The Company acknowledged the patent and accepted a licence.

You mean the Edison Company "knocked under"?—Yes.

WITNESS then described the state of knowledge about electric lighting in 1878, and explained the difference between lamps arranged in series and in parallel. He explained that there was an important and essential difference in the idea disclosed in his patent. That was for a fixed current dividing itself into branches, whereas in his specification he thought he might safely say that a new idea was introduced unthought of at that date—the idea of a constant potential with a variable load.

The ATTORNEY-GENERAL:—For the purpose of "earth return" it does not make any difference whether the return is insulated or not?—It does not.

Mr. JUSTICE A. L. SMITH: What is an uninsulated wire?

The ATTORNEY-GENERAL: An uncovered wire; it would be what you may call a more ready path. May I put the question, my lord? Do substances vary in their conductivity?—Yes.

For instance, wood is either no conductor at all or a bad conductor?—Very bad.

Metal is very good?—Very good.

Mr. JUSTICE A. L. SMITH: What does he call the difference between an insulated return and an uninsulated return?

The ATTORNEY-GENERAL: Would a strip of copper put through the ground coming back from the lamp to the generator be an uninsulated return?—Quite so.

Would the electricity in fact pass back, as far as you know, through that copper?—Unless some of it leaked out.

Mr. JUSTICE A. L. SMITH: Now about an insulated one.

The ATTORNEY-GENERAL: Now, then, what would be an insulated return? Take the same strip of copper, what would you do with it to make it an insulated return?—I should surround it with some material like gutta-percha, through which the current will not pass. From the point of view of getting the current back to the generator, it does not make a particle of difference whether it comes back through an insulated return or an uninsulated return.

Now I call your attention, if you please, to the next line as it now stands—"The electromotive force of the electric conducting mains should be kept as nearly as possible constant at, say, 100 volts, or British Association units of electromotive force." First, are you aware of any English enunciation of the 100 volts as being about the right standard prior to your patent?—No.

You believe that was the first time that that direction had been enunciated?—Yes.

And you direct here that it may be kept as nearly as possible constant at, say, 100 volts. I wish to ask you this, does your present experience tell you whether that is about the right standard or not?—It is the standard universally adopted at the present day.

Is it the pressure at which the defendants, as well as a number of other companies, work the incandescent electric light now?—It is.

I wish to ask you, was your direction the result of your own experiment and research?—It was.

WITNESS then described Planté's battery and Faure's improvements. The Faure, which had flannel or felt to keep the oxide up by the side of the plate, was a type which was supposed at one time to be going to be very useful, but which has been entirely discarded. During the years 1881, 1882, 1883, and 1884, people were trying to use the improved batteries rather than using the Planté batteries.

The ATTORNEY-GENERAL: Now to-day, speaking with all your knowledge of to-day, which are the best for the purposes described in that specification? Planté's lead and sulphuric acid, or the pasted batteries which were referred to by Prof. Perry?—Planté's are the best.

Planté was the original discoverer, I think?—Yes.

Which do the defendants use? Do they use Planté's or the pasted?—They use Planté's.

The secondary batteries act as a regulator both when current is going into them and when the current is going out of them. You point out that the cells should have "a very large conducting surface." Will you tell my lord why? That is on page 4 at line 54.—I said that they should have a very large conducting surface, because the larger the surface the more readily they respond to any change in the pressure, so as to prevent it rising or falling, as it would otherwise.—The conducting surface may be increased by increasing the extent or area of the plates immersed in the liquid.

FRIDAY, FEBRUARY 26th.

The examination of Mr. LANE FOX by the ATTORNEY-GENERAL being continued, he said that as far as he knew, either from his then knowledge or present knowledge, there had been no publication of the use of Planté's batteries as regulators of the electric light at all.

Digitized by Google

The ATTORNEY-GENERAL: Any publication of the use of Planté's batteries as regulators of the electric light at all?—No, there had not.

Had there been any use, or publication of the use, of secondary batteries as regulators in connection with any electric lighting at all?—No, nor, as far as I know, as regulators for keeping constant electromotive force in any shape or form whatever or electric pressure.

Mr. JUSTICE A. L. SMITH: Do I understand you to say that, prior to your patent, an electric light was always a variable light?—Yes.

The ATTORNEY-GENERAL: Your lordship has anticipated my next question, if I may put it in the form of a question; but perhaps you will take that first. Prior to your specification had anybody ever pointed out, to your knowledge, the necessity of maintaining a constant pressure with a varying light?—No, no one had.

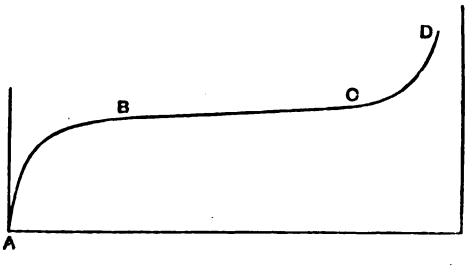
Now you point out the importance of putting several batteries at various points of the system. Do you know whether the Kensington and Knightsbridge Company, the defendants, have secondary batteries both at the stations and also at other places?—Yes, at both the station and a distance from the station. I believe it is somewhere in the neighbourhood of Queen's Gate.

Would you mind drawing in your own way a rough indication of the curve which is made of the pressure when you are charging secondary batteries to the full? Never mind if it is proportionately right, but draw a rough curve starting from half supply, or whenever you begin to charge, and then draw up to the full charging.—Charging with a fixed constant current?

Yes, charging with a fixed constant current.—It depends very much on that.

Sir HORACE DAVEY: They do not do that, I think.

The ATTORNEY-GENERAL: Well, I am not clear on that, but we will take it charging with a fixed constant current. Will you put A at the bottom, where you begin, B at the shoulder, the next point, and C where it begins to turn up, and D at the top?



The ATTORNEY-GENERAL: That shows the pressure rising from A right up to D?—Quite so.

What about would the pressure be when the pressure had fallen to the point C in your diagram?—About 2·1.

Now, at the point which you have indicated roughly as the point B, what would the pressure be, that is far away to the left?—Approximately 2 volts.

How much longer would it take to fall from C to B than from D to C?—Six or seven times. For ordinary working it would be kept between B and C.

As I will call it, on the plateau?—Yes.

Mr. JUSTICE A. L. SMITH: You mean they would be kept charged?—Yes, between these points. The closer the margin the more economical the working. The less variation, which implies waste of energy, the more economical it is. It is considered empty at B.

The ATTORNEY-GENERAL: Now, was this fact that there was at the beginning of charging this steep rise, then the plateau, and then at the end the sudden rise, perfectly well known?—Yes, it was described by Planté.

Now, if the batteries were worked in the way described, that is to say, excess current put into them during the hours of little draft to feed the mains during the hours of what I may call extra draft, would those batteries ever get off what you have called the plateau?—They would not. No.

If your direction was disregarded, namely, that the cells would not have a very large conducting surface, would it then be possible that the batteries would be too small and would not give a sufficient supply?—Quite so, the curve would slant more.

Quite so. And between the points B and C, assuming the generators to be working and the batteries working between B and C, would that or would it not keep the pressure at the lamps constant?—It would keep the pressure practically constant.

WITNESS then described the temporary lighting of Lady Conyers' house, 108, Queen's-gate, in the spring of 1882. Batteries were lent by Mr. Sellon. Lane Fox lamps were used, a steam engine was placed in an empty shop, and wires were carried over the tops of the houses. The lighting of the Brush offices at Belvedere-road, Lambeth, was carried out on the Lane Fox system in 1882: a dynamo, steam engine, and E.P.S. batteries were used, but no electrical governor. Uninsulated returns were used. There was no change or alteration in that installation in consequence of any failure of the system to maintain a constant pressure. Between 1882 and 1885 the then pasted plates of the batteries were giving a great deal of trouble, owing to the peroxide of lead which had been mechanically fastened to the plates becoming loose and dropping off. It was due to bungling—stupid workmen. Since then those pasted batteries have been largely improved and discarded. Witness then described an installation for the lighting of the Imperial Opera House in Vienna in 1883, and alluded to another which has been exceedingly successful at the King of Roumania's Palace at Senar, near Bucharest, in the Carpathian Mountains.

What companies in London are now adopting that system which is described in your patent?—The defendants', the Kensington and Knightsbridge Electric Lighting Company, the Westminster Electric Lighting Company, which is in combination—there is a trade association combined to fight this patent—the Notting Hill, the Metropolitan, the St. James's, and a great number of provincial companies.

What companies have taken licences?—The Edison Manchester have made an arrangement with the Brush Company when my patents were in their hands. I do not know much about that. They took a licence. There was a valuable consideration. What the valuable consideration was they would not disclose to me, because it raises a question in the agreement. It led to a compromise.

In reply to further examination, WITNESS said that he got back the patents into his own hands some two years ago. He was not in a position to enforce them until then. This action commenced in 1890. He had inspected the defendants' works. His system was being employed. They were using batteries connected up at various points with the mains, so that by increasing the electromotive force during the hours when not much electricity is being used they will become charged, and the electric force will be stored up in them, so that a sufficient supply will be available when the electromotive force fails, owing to the draft from the mains when the force is most used and needed; but there is just the fact that they do use a switch arrangement.

The ATTORNEY-GENERAL: During that time (whether it is an hour or two hours or more) that the number of cells remains switched in, is the operation the same as in your patent?—Exactly. The regulation goes on exactly the same.

After they switched out a number and there is a less number, does your patent describe the operation exactly with a less number of cells?—Exactly; it could not do otherwise.

What is the object of switching in and switching out cells?—The object of switching in is to make a battery of small capacity do the work of a battery of large capacity by wasting a certain amount of energy. If they had a larger amount of surface area in each cell, or a larger number of cells, it would not be necessary to switch in and switch out so often. With the battery they use the variations of the potential would be greater unless they switched cells in and out. It is not a necessity. It is a matter of expediency. The cells are called the Crompton Howell, and they are very good cells indeed. They are practically Planté cells with such modifications in detail as the exigencies of manufacture suggest.

The remainder of the examination in chief related to the patents of Achard and Clark.

In cross-examination, Sir HORACE DAVEY asked whether, in 1878, Mr. Lane Fox was not quite a youth, twenty years old or something like that. He replied that he was now 35; he had at that time already taken out several patents, and mentioned that he was then on the Council of the Institution of Electrical Engineers. He had been engaged in practical manufacture of electrical apparatus at his own works before 1878. He had works in Hatton-garden, and an office in the City. Questioned on Staite's patent, 11,783, of 1847, where it is said that "a good degree of intensity to use is such as would be afforded by 100 cells in a series of the usual sort employed in galvanic apparatuses," he said that this would be approximately 100 volts. But he thought that it was quite accurate to say that his specification was the first suggestion that a 100-volt current was the most suitable current for incandescent lighting. He did not say for electric lighting, but electrical distribution as described in the patent. He was not speaking vaguely of electric lighting when he made that remark.

I am not going into the merits of your lamp. It may, for aught I know to the contrary, be a most perfect lamp.—These are all my lamps in a sense. It is a matter merely of detail of construction. The principles on which all these lamps are constructed are actually enunciated in my patent.

In your patent of 1878?—In my patent of 1878.

And you claim all the lamps which we see around us at the present moment as being within your specification?—As coming within this specification. The Edison Company have acknowledged the validity of my patents, and all these lamps are now licensed under my patents—every one of them. There was an action brought in respect of infringement which was compromised. Before Mr. Justice Kay the judgment was to the effect that I had anticipated Edison in all particulars. That judgment was reversed.

I will allow you to say so. I do not think that is quite accurate; but the Court of Appeal did not take that view?—No.

Mr. JUSTICE A. L. SMITH: You say that these lamps were made by Edison's. Do I understand you aright that these lamps are now being used under licence from you?—From the Brush Company. Yes, under licence under my patents. I derive no benefit personally from them.

Sir HORACE DAVEY: The Brush Company brought an action against the Edison Company founded on several patents of yours, and that action was discontinued?—I was unable to ascertain the exact terms, but I believe the Edison Company waived their claim for damages against the Brush Company, and that was a very substantial amount. I do not remember the exact terms. I was never in Court. A royalty is paid of a farthing for every lamp manufactured by the Edison Company to the Brush Company. I had to ratify that licence. That is under a patent of 1880 for improvements, not under this patent of 1878.

In further cross-examination as to details, WITNESS said that the lamp was described in the present patent, not in detail but broadly. He admitted that the lamps used by the defendants did not contain iridium or platinum, but that was not essential, it was a matter of preference. After examination on the desirability of an electric regulator, and the use of gas and water pipes as "earth," he said that a current of 100 amperes would require an altogether unwieldy size of earth plate. They could not get one earth plate; they would have to divide it up into a great number, and these

Digitized by Google

would have to cover a very large surface The question was how much energy they were prepared to lose in resistance, but he said that the size would be unwieldy. Over great distances there might be an advantage. The distance from the lamps to the generator being a mile, they might begin to get advantages from the use of an earth return. He should say a soil return, because he made an important distinction between a soil return and an earth return, as described in the specification. At a short distance the use of a soil return would be ridiculous ; no one would think of using such a thing.

Now I will ask you to look at your figure 5.* I daresay you are familiar with figure 5, which is intended to represent on an extremely condensed scale the whole system, is it not?—Yes. It is intended to represent the whole system in a diagrammatic fashion.

You have your generator, and the negative pole of your generator goes to "earth," does it not?—Yes.

And by this slightly circular kind of thing with "earth" written on it, did you not intend to describe the soil?—I did not ; I had not the smallest intention of describing the soil.

Is not the way in which an electrical engineer would ordinarily describe a terminal going to earth by an earth plate?—He would describe it in that way, and he would describe all earths in that way : he would represent all earths whatsoever in that manner. He would say that an insulated conductor was an equivalent of an earth return, but not identical. If an insulated conductor answered the purpose it would be included certainly in the words "the earth." There is a distinction between saying insulation is unnecessary and insulation must not be.

After considerable examination as to the use of batteries,

Mr. JUSTICE A. L. SMITH : What I understand you to say is this, that this specification meant that, as it is stored up, and as it is wanted either to increase or decrease, it is let out automatically?—Quite so, it is available there by means of the connections described.

Sir HORACE DAVEY : I understand that, but then the purpose for which you require your electricity is for the purpose of supplementing the current of the mains?—Yes, it is so. That is one purpose. The advantage of having a reserve store there in case anything happens to the engine is an obvious purpose which is additional.

The sole way in which you have used your reservoir is exactly that in which Planté intended it to be used—namely, to store up electricity, and to let the electricity flow from it when it is wanted?—Planté never contemplated the combination described in this specification.

Mr. JUSTICE A. L. SMITH : Planté never suggested an automatic letting out or taking in?—Never, my lord.

Sir HORACE DAVEY : Yes, my lord.

The WITNESS : Not the slightest.

Mr. JUSTICE A. L. SMITH : I have not seen that yet anyhow—not automatically.

Sir HORACE DAVEY : Yes.

Mr. JUSTICE A. L. SMITH : It may be so, but I cannot see anything about it.

Sir HORACE DAVEY : There is nothing in its being automatic—whether you turn off a tap automatically or not.

Mr. JUSTICE A. L. SMITH : I should say that made all the difference in the world, if you asked me, whether a thing acted by itself or whether a man must intervene and turn a tap.

Sir HORACE DAVEY : These Kensington people do not use that automatically?—Indeed they do. They turn it on and off as they want it.

Mr. JUSTICE A. L. SMITH : Who?—Planté?

Sir HORACE DAVEY : No, the Kensington people—the defendants.

Mr. JUSTICE A. L. SMITH : With their switches?

Sir HORACE DAVEY : Yes ; I say they turn it on and off as they want it. They do not use it automatically.

Mr. JUSTICE A. L. SMITH : I know ; but he gives the go-by to their switching.

Sir HORACE DAVEY : I think your lordship will find that is the point.

Mr. JUSTICE A. L. SMITH : I know what is coming perfectly well. I see the case, but I say as far as Mr. Lane Fox goes he gives the go-by to the switches and everything else.

Sir HORACE DAVEY : I know he does, but I hope before I have done to convince your lordship that without the switching——

Mr. JUSTICE A. L. SMITH : All that I said was that, in my judgment, an invention which would let out this current automatically was not identical with a storage of the current which you would have to go and put your finger on to let out. That is all I said. It would take a great deal to induce me to think that they are identical, Sir.

Sir HORACE DAVEY : Now let us go back to the point. I have had an elementary text-book put into my hands. I do not know if you will recollect it, it is a practical handbook by Sir David Salomons, Bart., Vice-President of the Institution of Electrical Engineers, published in the year 1891. It is on "Electric Light Installation and the Management of Accumulators." I find in the very first sentence in Chapter 6 this :—"Always charge the cells until they boil well." Well, they will not boil well until they are completely charged, will they?—No, he was referring particularly to the E.P.S. cells I think, which do require boiling, so to speak. They are a development which I say was a bad development for Planté purposes. It required special attention and care to keep them in order.

How do you know that this gentleman is talking of E.P.S. cells?—Because I think, if I remember rightly, he is a Director of that Company

Then your view is that you must find out by experiment when you are to cease charging. Is that so?—By observation. It would be perfectly manifest to an attendant with common sense if he was sober.

I do not know if that is meant for a joke.—I say that if he was in attendance there, and he knew what his business was, he would turn off steam when there had been enough work done.

* *The Electrician* Feb. 26th, p. 438.

I suppose you would say that Mr. Crompton was a person of intelligence, would not you?—I have had great difficulty in cramming the A.B.C. of the subject into his head. I found him very dense at one time.

You thought Mr. Crompton very dense?—At one time he was very dense and very obstinate. He said the whole thing was nonsense, and it would not work. He pooh-poohed the whole subject, and I had strong arguments with him to convince him that the thing was practical. He said the whole thing was an absurdity at one time.

After a long cross-examination on the use of batteries, Mr. LANE FOX was questioned about an installation by Mr. Crompton at the Law Courts. This was put in in 1882, and was alleged to be in accordance with the present specification.

Sir HORACE DAVEY : And Edison lamps, I think, were used?—I think they were called Swan lamps. I think they were practically the same lamps as were made here.

They were incandescent carbon lamps?—Yes.

I will not dispute with you whether they were Edison or Swan.—I might have taken an interest in that some time ago, but I do not now take the faintest.

Mr. MOULTON : At that time they were two different kinds of lamps.

Sir HORACE DAVEY : Excluding the lamps for a moment, if I have described it rightly, that was exactly your system, was it not?—Yes.

Sir H. DAVEY suggested that within the first week after the accumulators and generators were started, at one time it was found practically that when the batteries were being charged the lamps flared up, and in one instance one broke with a loud bang, and frightened the Court and the judges and everybody else ; and that when the batteries were being discharged the potential fell, and the lamps became red bars, and gradually went out?—Witness could not remember being consulted by Mr. Crompton as to what should be done.

In reply to further questions, the WITNESS stated that on October 12th, three days after the other patent, he took out a patent in which he described commutators to be used with batteries :—"So that it will not be necessary to increase the electromotive force in the mains in order to charge them, but by merely coupling two or more parts or the whole battery for 'quantity' they can be charged with a low electromotive force, and be capable of giving by an alteration of the commutators the full tension when required." The idea occurred to him afterwards, as an alternative to the process described just above, where a smaller battery would do the same work as an improvement. The St. James's Company are using batteries without altering the number of cells, and it is a far more successful installation than the Kensington and Knightsbridge. The potential there is kept much more nearly constant. At the Vienna Opera House there was an elaborate arrangement for adjusting the current by means of switches, far more elaborate than that at Kensington, but this was for producing special scenic effects. There was a similar arrangement of apparatus for switching on and off cells at the King of Roumania's installation. He invented them. Prof. Perry invented them five years afterwards, and Mr. Crompton did eight years afterwards. He invented them first.

MONDAY, FEBRUARY 29TH.

In reply to further cross-examination by Sir HORACE DAVEY, Mr. LANE FOX said that at the Opera House at Vienna there was a large number of different batteries for working circuits and producing different effects, and it may be that there were distinct batteries for working a different number of lamps, and that those batteries may have been worked quite independently, for the time being, of the dynamos. It was a very large installation, and very complicated. The work was carried out by his assistants, and he never visited the Opera House for the purpose of arranging it. The voltage in the mains was 90, but two 45-volt lamps were put together in series.

Do you know if that was so?—Probably it was so ; as a matter of fact one lamp was divided into two ; one lamp was made with two filaments instead of one.

At Lady Conyers' it was a specially prepared installation for that particular night?—Yes ; not specially prepared for that night ; it was specially installed for that night. There were no special requirements to suit the occasion. It was a very different case from the Opera House. The batteries were sent up to Queen's Gate ready charged, but they continued charging them after they had been set down.

You had to supplement the charge, but they were charged?—They happened to be charged batteries that were sent up. The process of charging and discharging continued during the whole of the installation, more or less ; it depended on the pressure of the steam engine and the number of lamps. He had no measuring instruments, but estimated the quantity of current. The pressure gauge of the engine gave a very good indication of what the dynamos were doing. The instrument for indicating the potential was the brilliancy of the lamps ; those are to me a very exact indication.

I ought to put this accurately, or you will be down upon me. Was your steam engine of sufficient horse-power to make the dynamos produce a current sufficient to light them?—The engine could have developed sufficient power. Did it?—Not during the whole time.

What was the voltage on that occasion?—I cannot say exactly ; it depends on the lamps we had available.

That is quite true, but cannot you tell me whether it was 100 or anything like 100?—I think it was 75, but I cannot be certain.

Mr. JUSTICE A. L. SMITH : I think you told me how many lamps you had going, but I do not remember.—I think about 50.

The ATTORNEY-GENERAL : Yes ; he stated it in chief. Might I, as there is a break, give your lordship the specification as I promised it, showing what was cut out in blue in the first one, and what was cut out in red in the second? [*Handing it in.*]

Mr. JUSTICE A. L. SMITH : He strikes out generally the lamp and the engine regulator.

Questioned by Sir HORACE DAVEY as to his connection with the Brush Company, Mr. Lane Fox said that he filled different capacities from 1881 to 1889, and different agreements took place between them at different times. At first he was manager of what they called the Lane Fox department. It was a department specially devoted to incandescent lighting as opposed to arc lighting. He did not know whether batteries were introduced later or introduced at once in the installation at the offices, he could not be sure.

And after the accumulators were introduced was it found necessary, in order to make the installation work, to add switches and other devices for regulating the cells?—That I altogether deny: "found necessary" is an improper expression.

Now, the Brush Company was a wealthy, powerful corporation, was it not?—Yes.

And if I may draw upon my own experience, they were not afraid of litigation?—Well, I rather think they were.

Can you tell me how it is that you, having charge of the Lane Fox department, did not push this patent of yours of 1878?—I did, but the pressure against which I had to push was tremendously powerful.

The electro-motive force was too much?—There was a very strong opposing influence, due to causes which I will relate, if necessary.

Is that the only reason you can give me for this patent not having been apparently brought into use?—It is *the* reason.

It is this reason why the patent was not apparently brought into practical use?—It was brought into practical use, but my merit and my rights in the matter were successfully suppressed.

Do you suggest by the Brush Directors?—I would rather not go into invidious matters if it is not necessary. A certain sum of money, £5,000 in fact, was paid to the British Electric Light Company for foregoing a certain claim which they had, which, though not a legal claim, was considered of sufficient importance to enable them to be very obstructive. The British Electric Company had from me certain letters which gave them claims, as they said, upon my patents. No cash whatever, apart from that sum, was paid to me personally.
